(*b*) Technically, a definite compensation or return reserved by a lease, to be made periodically, or fixed with reference to a period of tenure, and payable in money, produce, or other chattels or labor, for the possession and use of land or buildings. Compensation of any other nature is not termed *rent*, because not enforceable in the same manner. The time of paying rents is either by the particular appointment of the parties in the deed, or by appointment of law, but the law does not control the express appointment of the parties, when such appointment will answer their intention. In England Michaelmas and Lady-day are the usual days appointed for payment of rents; and in Scotland Martinmas and Whitsunday.

> Take (deer Son) to thee
> This Farm's demains, . . .
> And th' only *Rent* that of it I reserue is

Rent is said to be due at the first moment of the day appointed for payment, and in arrear at the first moment of the day following. *Encyc. Brit.*, XIV. 275.

(*c*) The right to such compensation, particularly in respect of lands. Rents, at common law, are of three kinds; *rent-service, rent-charge* or *fee-farm*

rent, and *rent-seck*. *Rent-service* is when some corporal service is incident to it, as by fealty and a sum of money; *rent-charge*, or *fee-farm rent*, is when the owner of the rent has no future interest or reversion expectant in the land, but the rent is reserved in the deed by a clause of distress for rent in arrear (in other words, it is a charge on lands, etc., in the form of rent, in favor of one who is not the landlord); *rent-seck* is a like rent, but without any clause of distress. There are also *rents of assize*, certain established rents of freeholders and copyholders of manors, which cannot be varied: also called *quit-rents*. These, when payable in silver, are called *white rents*, in contradistinction to rents reserved in work or the baser metals, called *black rents* or *black mail*.

3. In *polit. econ.*, that part of the produce of the soil which is left after deducting the wages of labor (including often various payment in kind, as food, house-room, etc.), the interest on the necessary capital, and replacement of materials destroyed, as seed and the perishable elements of fertility in the soil; that part of the produce of a given piece of cultivated land which it yields over and above that yielded by the poorest land in cultivation under equal circumstances in respect to transportation, etc. The rent theoretically goes to the owner of the soil, whether cultivator or landlord. Also called *economic rent*. In modern political economy there is a tendency to use the term in a much wider sense, some economists including payments for the use of all concrete goods, the payment being reckoned as a lump sum, and thus in contrast with interest reckoned as a percentage of a capital sum. Other economists are disposed to class as rents all incomes which may be ascribed to differential advantage in production. Thus monopoly profit is sometimes called a rent, as is also the profit secured through superior management; and even the excess of wages of superior over inferior labor has been so classed.

Rent is that portion of the produce of the earth which is paid to the landlord for the use of the original and indestructible powers of the soil. It is often, however, confounded with the interest and profit of capital.
Ricardo, Polit. Econ., ii.

The *rent*, therefore, which any land will yield, is the excess of its produce beyond what would be returned to the same capital if employed on the worst land in cultivation.
J. S. Mill, Polit. Econ., II. xvi. § 3.

=Syn. *Repentance, Penitence, Contrition, Compunction, Regret, Remorse*, may express the sorrowful feeling of the wrong-doer in view of his conduct. *Regret* is quite as often used of wishing that one had not done that which is unwise; as applied to misconduct, it expresses the feeblest degree of sorrow for doing wrong; but it may contain no element of real *repentance*. *Repentance* goes beyond feeling to express distinct purposes of turning from sin to righteousness; the Bible word most often translated *repentance* means a change of mental and spiritual attitude toward sin. Strictly, *repentance* is the beginning of amendment of life; the word does not imply any greater degree of feeling than is necessary to bring about a change, whether the turning be from a particular sin or from an attitude of sin. *Penitence* implies a large measure of feeling, and applies more exclusively than *repentance* to wrong-doing as an offense against God and right. *Contrition*, literally breaking or bruising, is essentially the same as *penitence;* it is a deep, quiet, and continued sorrow, chiefly for specific acts. *Compunction*, literally pricking, is a sharp pang of regret or self-reproach, often momentary and not always resulting in moral benefit. It is more likely than remorse to result in good. *Remorse*, literally gnawing, is naturally sharper mental suffering than *compunction;* the word often suggests a sort of spiritual despair or hopelessness, paralyzing one for efforts to attain repentance.

See *repoussé*, *n.*—**2.** In *etching*, the hammering out from behind of parts of an etched plate which have been brought by charcoal or scraper below half its thickness, making hollows which would show as spots in printing, in order to bring them up to the required level. A spot to be thus treated is fixed by letting one of the points of a pair of calipers (compasses with curved legs) rest on the place, and marking the corresponding place on the back of the plate with the other point.

C. T. Newton, Art and Archæol., p. 381.

II. *n.* Repoussé work; the art of shaping vessels and the like, and of producing ornament on the surface, by hammering thin metal on the reverse side, the artist watching the side destined to be exposed to follow the development of the pattern by the blows of the hammer; also, the articles thus produced. A hammer with an elastic handle screwed to a permanent support, and having many adjustable heads, is used for this work. Repoussé work is often finished by chasing; the chaser, working upon the right side of the metal, presses back or modifies the relief of the metal, which has taken shape from the hammer. For this purpose a bed of some resistant but soft material is provided to support the metal while in the chaser's hands: hollow silver vessels, for instance, are filled with pitch. Compare *chasing*.

Specifically—(*a*) In *insurance* and *law*, a verbal or written statement made on the part of the insured to the insurer, before or at the time of the making of the contract, as to the existence of some fact or state of facts tending to induce the insurer more readily to assume the risk, by diminishing the estimate he would otherwise have formed of it. It differs from a warranty and from a condition expressed in the policy, in being part of the preliminary proceedings which propose the contract, and its falsity does not vitiate the contract unless made with fraudulent intent or perhaps with respect to a material point; while the latter are part of the contract when completed, and non-compliance therewith is an express breach which of itself avoids the contract. (*b*) In *Scots law*, the written pleading presented to a lord ordinary of the Court of Session when his judgment is brought under review.

5. An expostulatory statement of facts, arguments, or the like; remonstrance.

> He threatened "to send his jack-boot to rule the country," when the senate once ventured to make a *representation* against his ruinous policy. *Brougham.*

6. In *psychol.*, a word often employed to translate the German *Vorstellung*, used in that language to translate the English word *idea*. See *idea*, 2 and 3. (*a*) The immediate object of cognition; anything that the mind is conscious of. This is now the commonest meaning of *Vorstellung*, and recent translators have most frequently rendered it by the word *idea*. (*b*) A reproduced perception.

H. Lewes.*

7. In *law:* (*a*) The standing in the place of another, as an heir, or in the right of taking by inheritance; the personating of another, as an heir, executor, or administrator. (*b*) More specifically, the coming in of children of a deceased heir apparent, devisee dying before the testator, etc., to take the share their parent would have taken had he survived, not as succeeding as the heirs of the parent, but as together representing him among the other heirs of the ancestor. See *representative*, *n.*, 3. In Scots law the term is usually applied to the obligation incurred by an heir to pay the debts and perform the obligations incumbent upon his predecessor.

8. Share or participation, as in legislation, deliberation, management, etc., by means of regularly chosen or appointed delegates; or, the system by which communities have a voice in the direction of their own affairs, and in the making of their own laws, by means of chosen delegates: as, parliamentary *representation*.

> The reform in *representation* he uniformly opposed.
> *Burke.*

He [Daniel Gookin] was the originator and the prophet of that immortal dogma of our national greatness — no taxation without *representation*.
M. C. Tyler, Amer. Lit., I. 154.

As for the principle of *representation*, that seems to have been an invention of the Teutonic mind; no statesman of antiquity, either in Greece or at Rome, seems to have conceived the idea of a city sending delegates armed with plenary powers to represent its interests in a general legislative assembly. *J. Fiske*, Amer. Pol. Ideas, p. 59.

In these small [Grecian] commonwealths *representation* is unknown; whatever powers may be entrusted to individual magistrates or to smaller councils, the supreme authority must rest with an assembly in which every qualified citizen gives his vote in his own person.
E. A. Freeman, Amer. Lects., p. 246.

9. A representative or delegate, or a number of representatives collectively.

The *representations* of the people are most obviously susceptible of improvement. *J. Adams*, Works, IV. 284.

Proportional representation, representation, as in a political assembly, according to the number of electors, inhabitants, etc., in an electoral district or other unit. This principle is recognized in the United States House of Representatives and in many other bodies, especially those of a popular character.—**Pure representation.** See *pure.*—**Syn. 3.** Show; delineation, portraiture, likeness, resemblance.

representational (rep″rē-zen-tā′shọn-ạl), *a.* [< *representation* + *-al.*] Pertaining to or containing representation, in any sense; of the nature of representation.

We find that in "constructive imagination" a new kind of effort is often requisite in order to dissociate these *representational* complexes as a preliminary to new combinations. *J. Ward*, Encyc. Brit., XX. 57.

representationary (rep″rē-zen-tā′shọn-ā-ri), *a.* [< *representation* + *-ary.*] Of or pertaining to representation; representative: as, a *representationary* system of government. [Rare.]
Imp. Dict.

representationism (rep″rē-zen-tā′shọn-izm), *n.* [< *representation* + *-ism.*] The doctrine, held by Descartes and others, that in the perception of the external world the immediate object of consciousness is vicarious, or representative of another and principal object beyond the sphere of consciousness.—**Egoistical representationism.** See *egoistic.*

representationist (rep″rē-zen-tā′shọn-ist), *n.* [< *representation* + *-ist.*] One who holds the doctrine of representationism.

The *representationists*, as denying to consciousness the cognisance of aught beyond a merely subjective phænomenon, are likewise idealists; yet, as positing the reality of an external world, they must be distinguished as cosmothetic idealists. *Hamilton*, Reid's Works, Note C, § 1.

representative (rep-rē-zen′tạ-tiv), *a.* and *n.* [< F. *représentatif* = Pr. *representatiu* = Sp. Pg. *representativo* = It. *rappresentativo*, < ML. *repræsentativus*, < L. *repræsentare*, represent: see *represent.*] **I.** *a.* **1.** Representing, portraying, or typifying.

Representative [poesy] is as a visible history, and is as image of actions as if they were present, as history is of actions in nature as they are, (that is) past.
Bacon, Advancement of Learning, ii.

They relieve themselves with this distinction, and yet own the legal sacrifices, though *representative*, to be proper and real. *Bp. Atterbury.*

Men have a pictorial or *representative* quality, and serve us in the intellect. Behmen and Swedenborg saw that things were *representative*. Men are also *representative* — first, of things, and, secondly, of ideas.
Emerson, Representative Men, p. 14.

2. Acting as the substitute for or agent of another or of others; performing the functions of another or of others.

This council of four hundred was chosen, one hundred out of each tribe, and seems to have been a body *representative* of the people. *Swift.*

The more multitudinous a *representative* assembly may be rendered, the more it will partake of the infirmities incident to collective meetings of the people.
A. Hamilton, Federalist, No. 58.

3. Pertaining to or founded on representation of the people; conducted by the agency of delegates chosen by or representing the people: as, a *representative* government.

A *representative* government, even when entire, cannot possibly be the seat of sovereignty — the supreme and ultimate power of a State. The very term *representative* implies a superior in the individual or body represented.
Calhoun, Works, I. 190.

He [Cromwell] gave the country a constitution far more perfect than any which had at that time been known in the world. He reformed the *representative* system in a manner which has extorted praise even from Lord Clarendon. *Macaulay.*

4. In *biol.*: (*a*) Typical; fully presenting, or alone representing, the characters of a given class or group: as, in zoölogy and botany, the *representative* genus of a family.

No one human being can be completely the *representative* man of his race. *Palgrave.* (*Latham.*)

(*b*) Representing in any group the characters of another and different group: chiefly used in the quinarian system; also, pertaining to such supposed representation: as, the *representative* theory. (*c*) In zoögeography, replacing; taking the place of, or holding a similar position: as, the llama is *representative* of the camel in America.—**5.** In *psychol.* and *logic*, mediately known; known by means of a representation or object which signifies another object.

The chief merit or excellence of a *representative* image consists in its distinctness or clearness.
J. Sully, Outlines of Psychol., p. 227.

Representative cognitions, or those in which consciousness is occupied with the relations among ideas or represented sensations, as in all acts of recollection.
H. Spencer, Prin. of Psychol., § 480.

Representative being, being as an immediate object of consciousness.—**Representative faculty**, the faculty of representing images which the reproductive faculty has evoked; the imagination.—**Representative function**, a function having the properties of $\phi(a, n)$, stated below, under *representative integral.*—**Representative integral**, an integral of the form

$$\int_A^b f\alpha \cdot \phi(\alpha, n) \cdot d\alpha,$$

where $f\alpha$ is a function of limited variation between A and another limit, B, exceeding b, while $\phi(\alpha, n)$ is (1) such a function of α and the parameter n that the integral of it between the same limits is less than an assignable finite quantity, whatever value between A and B be given to b, and whatever value be given to n; and (2) is such that when n tends toward infinity, the integral of $\phi(\alpha, n)$ from A to b, where b is greater than A and less than B, tends toward a constant finite value. This is called a *representative integral*, because it is equal to the function fA multiplied by a constant.—**Representative knowledge**, knowledge of a thing by means of a mental image, but not as actually existing.—**Representative primogeniture.** See *primogeniture.*

II. *n.* **1.** One who or that which represents another person or thing; that by which anything is represented or exhibited.

This doctrine supposes the perfections of God to be *representatives* to us of whatever we perceive in the creatures.
Locke.

A statue of Rumour, whispering an idiot in the ear, who was the *representative* of credulity. *Addison*, Freeholder.

This breadth entitles him [Plato] to stand as the *representative* of philosophy.
Emerson, Representative Men, p. 44.

2. An agent, deputy, or substitute, who supplies the place of another or others, being invested with his or their authority: as, an attorney is the *representative* of his client or employer; specifically, a member of the British House of Commons, or, in the United States, of the lower branch of Congress (the House of Representatives) or of the corresponding branch of the legislature in some States.

Then let us drink the Stewartry,
Kerroughtree's laird, and a' that,
Our *representative* to be.
Burns, Election Ballads, i.

The tribunes of Rome, who were the *representatives* of the people, prevailed, it is well known, in almost every contest with the senate for life.
A. Hamilton, Federalist, No. 63.

There are four essentials to the excellence of a representative system: — That the *representatives* . . . shall be *representatives* rather than mere delegates.
Bryce, Amer. Commonwealth, I. 296.

3. In *law*: (*a*) One who occupies another's place and succeeds to his beneficial rights in such a way that he may also in some degree be charged with his liabilities. Thus, an heir or devisee, since, to the extent of the property to which he succeeds, he is liable for his ancestor's debts, is a *representative* of the ancestor; but the widow, who takes part of the estate as dower, without liability, is not deemed a *representative* of the deceased; nor is an officer or trustee who succeeds to the rights and powers of the office or trust a *representative* of his predecessor, for, though he comes under liability in respect of the office or trust as his predecessor did, he does not succeed to the liabilities which his predecessor had incurred. The executor or administrator is sometimes spoken of as the *representative* of the decedent, but is usually distinguished by being called the *personal representative.* (*b*) One who takes under the Statute of Descents or the Statute of Distributions, or under a will or trust deed, a share which by the primary intention would have gone to his parent had the parent survived to the time for taking. If a gift has vested in interest absolutely in the parent, then, upon the parent's death before it vests in possession, the child will take as successor in interest of the parent, but not as *representative* of the parent in this sense. But if the parent dies before acquiring any interest whatever, as where one of several heirs apparent dies before the ancestor, leaving a child or children, the other heirs take their respective shares as if the one had not died, and the child or children of the deceased take the share their deceased parent would have taken. In this case all who share are *representatives* of the ancestor in sense (*a*), and the child or children are also *representatives* of the deceased heir apparent in sense (*b*). 2. The act or process of restoring parts of an organism that have been destroyed or removed.

The question of the *Reproduction* of Lost Parts is interesting from several points of view in biology. *Mind*, IX. 415.

Specifically—**3.** The process whereby new individuals are generated and the perpetuation of the species is insured; the process whereby new organisms are produced from those already existing: as, the *reproduction* of plants or animals. (*a*) The reproduction of plants is effected either vegetatively or by means of spores or of seeds. Vegetative reproduction consists in the individualizing of some part of the parent organism. In low unicellular plants this is simply a process of fission, one cell dividing into two or more, much as in the formation of tissue, save that the new cells become independent. In higher plants this method obtains by the shooting and rooting of some fraction of the organism, as a branch, a joint of a rootstock, in *Begonia* even a part of a leaf; or through specially modified shoots or buds, as the gemmæ of some algæ, mosses, etc., the bulblets of some mosses, ferns, the tiger-lily, etc., the corms, bulbs, and tubers of numerous annual plants. The cells engaged in this mode of reproduction are simply those of the ordinary tissues. Very many, but not all, plants propagate in this manner; but all are capable of reproduction in other methods included under the term *spore-reproduction*, which is reproduction most properly so called. This is accomplished through special reproductive cells, each of which is capable of developing into an individual plant. These are produced either independently, or through the conjunction of two separate cells by which their protoplasm coalesces. These may also in a less perfect sense be called reproductive cells. Reproduction through the union of two cells is sexual; through an independent cell, asexual. Sexual reproduction proceeds either by conjugation (that is, the union of two cells apparently just alike, which may be either common vegetative cells or specialized in form) or by fertilization, in which a smaller but more active sperm-cell or male cell impregnates a larger, less active germ-cell or female cell. In cryptogamous plants both methods are common, and the reproductive cells are termed *spores*, or when of the two sexes *gametes*, the male being distinguished as *antherozoids*, the female as *oöspheres*. In flowering plants spore-reproduction is always sexual, fertilization becoming pollination, the embryo-sac in the ovule affording the female cell and the pollen-grain the male cell. But the union of these cells produces, instead of a detachable spore, an embryo or plantlet, which, often accompanied by a store of nutriment, is inclosed within an integument, the whole forming a seed. The production of seeds instead of spores is the most fundamental distinction of phanerogams. Spore-reproduction is consummated by the germination of the spore or seed, which often takes place after a considerable interval. (*b*) Among the lowest animals, in which no sex is recognizable, reproduction takes place in various ways, which correspond to those above described for the lowest plants. (See *conjugation*, *fission*, *gemmation*, and *sporulation*.) Among sexed animals, reproduction results from the fecundation of an ovum by spermatozoa, with or without sexual copulation, and with many modifications of the details of the process. (See *genesis*, 2, and words there given.) Many animals are hermaphrodite, containing both sexes in one individual, and maturing the opposite sexual elements either simultaneously or successively: such are self-impregnating or reciprocally fecundating, as the case may be. Reproduction may be effected also by a detached part of an individual, constituting a separate person (see *generative person*, under *generative*). Sexual may alternate with asexual reproduction (see *parthenogenesis*); but in the vast majority of animals, invertebrate as well as vertebrate, permanent and perfect distinction of sex exists, in which cases reproduction always and only results from impregnation of the female by the male in a more or less direct or intimate act of copulation, and extends to but one generation of offspring. The organs or system of organs by which this is effected are known as the *reproductive organs* or *system*. *Reproduction* is always exactly synonymous with *generation* (def. 1); less precisely with *procreation* and *propagation* in their biological senses. See *sex*.

4. That which is produced or revived; that which is presented anew; a repetition; hence, also, a copy.

The silversmiths . . . sold to the pilgrims *reproductions* in silver of the temple and its sculptures. *The Century*, XXXIII. 138.

See *asexual*, and def. 3, above. —**Empirical synthesis of reproduction**, an association by the principle of contiguity, depending on the associated ideas having been presented together or successively.—**Pure transcendental synthesis of reproduction**, an association of ideas such that one will suggest the other independent of experience, due to innate laws of the mind, and one of the necessary conditions of knowledge. —**Sexual reproduction.** See def. 3, and *sexual*.—**Synthesis of reproduction**, the name given by Kant to that association of ideas by which one calls up another in the mind.

reproductive (rē-prō-duk'tiv), *a.* [= F. *reproductif* = Pg. *reproductivo*, < ML. **reproductivus*, < **reproducere*, reproduce: see *reproduce*.] Of the nature of, pertaining to, or employed in reproduction; tending to reproduce: as, the *reproductive* organs of an animal.

Reproductive cells, in *bot.* See *reproduction*, 3 (*a*).—**Reproductive faculty**, in the psychology of Sir William Hamilton, the faculty of association of ideas, by virtue of which one suggests a definite other, but not including the faculty of apprehending an idea a second time.—**Reproductive function of order *n*.** See *function*.—**Reproductive imagination**, the elementary faculty by virtue of which one idea calls up another, of which memory and imagination, as popularly understood, are special developments. See *imagination*, 1.

Philosophers have divided *imagination* into two—what they call the *reproductive* and the productive. By the former they mean imagination considered simply as re-exhibition, representing the objects presented by perception—that is, exhibiting them without addition or retrenchment, or any change in the relations which they reciprocally held when first made known to us through sense. *Sir W. Hamilton*, Metaph., xxxiii.

Reproductive organs. (*a*) In *bot.*, the organs appropriated to the production of seeds or spores: in flowering plants, chiefly the stamens and pistils together with the accessory floral envelops; in cryptogams, mainly the antheridia and archegonia. (*b*) In *zoöl.*, those organs or parts of the body, collectively considered, whose function it is to produce and mature ova or spermatozoa or their equivalents, and effect the impregnation of the female by the male elements, or otherwise accomplish reproduction; the reproductive or generative system of any animal in either sex; the genitals, in a broad sense. The fundamental reproductive organ of all sexed animals is an indifferent genital gland, differentiated in the male as a testis, in the female as an ovary (or their respective equivalents); its ulterior modifications are almost endless. These organs are sometimes detached from the main body of the individual (see *person*, 8, and *hectocotylus*); they often represent both sexes in one individual; they are usually separated in two individuals of opposite sexes; they sometimes fail of functional activity in certain individuals of one sex (see *neuter*, *worker*).—**Reproductive system**, in *biol.*, the sum of the reproductive or generative organs in plants and animals; the generative system; the sexual system of those plants and animals which have distinction of sex. The term is a very broad one, covering not only all parts immediately concerned in generation, but others indirectly conducing to the same end, as devices for effecting fecundation, for protecting or nourishing the product of conception, for cross-fertilization (as of plants by insects), for attracting opposite sexes (as of animals by odorous secretions), and the like. See *secondary sexual characters*, under *sexual*.

I. WATER-MOCCASIN, *Ancistrodon piscivorus.*

Inhabits the southeastern portion of the United States, from central North Carolina southward throughout Florida and westward to Texas. It is the terror of the negroes in the rice-fields. Attaining a length of two to four feet, powerful in build, and with a vicious disposition, this is to be rated a highly dangerous reptile. It is semiaquatic, and has a habit of opening the mouth a few seconds before striking, thus displaying the white mouth-parts; hence one of its common names, the "cottonmouth" snake. Its food consists of small mammals, birds, frogs, and fish. The water-moccasin is one of the most abundant of the southern reptiles. Several species of large, innocuous water-snakes look much like it.

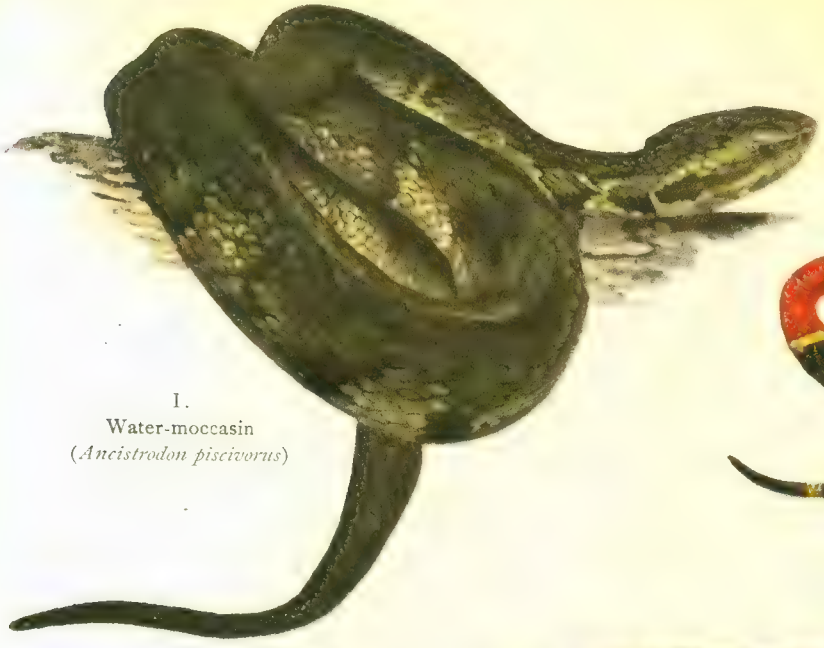
II. CORAL-SNAKE, *Elaps fulvius.*

Found in the southeastern portion of the United States. An allied species occurs in the Southwest. A burrowing species and in form much like the harmless serpents. It is related to the cobras of the Old World, and while the fangs are very small the poison is highly virulent. Fatal bites have been recorded. Owing to its secretive disposition, accidents are few. Unless stepped on, these snakes seldom attempt to bite. The food consists of other snakes and lizards.

III. DIAMOND-BACK RATTLESNAKE, *Crotalus adamanteus.*

Largest and deadliest of the North American poisonous serpents. Attains a length of six feet. The habitat embraces the southeastern portion of the United States, from South Carolina throughout Florida and westward to Texas. Lives in the hummock lands. Its markings harmonize with the vegetation, and it is difficult to distinguish. It quickly strikes when disturbed. The bite is usually fatal unless the most skilful treatment is immediately employed. Its food consists of rats, rabbits, and quail.

IV. TIMBER RATTLESNAKE, *Crotalus horridus.*



Inhabits the timbered regions of the eastern United States, from the Atlantic coast to the Mississippi River, ranging from northern New York southward into Florida. Attains a maximum length of five and a half feet. The females are usually yellow, banded with black; the greater number of the males are blackish. This is not so vicious a snake as the big diamond-back rattler, and as it is considerably smaller its bite is not so dangerous. This and the copperhead snake are the only poisonous reptiles inhabiting the Eastern States north of central North Carolina.

V. COPPERHEAD SNAKE, *Ancistrodon contortrix.*

Owing to its pattern of light and dark brown hues, the copperhead is difficult to distinguish if among dead fallen leaves. It is not particularly vicious, and usually seeks to escape when disturbed. It is seldom found far from timbered areas. A large copperhead is three feet long. The bite is not so dangerous as that of a rattlesnake, owing to the reptile's smaller size and its proportionately shorter fangs. These snakes are yet found on the Palisades of the Hudson River. The habitat covers the eastern portion of the United States, from southern Massachusetts to northern Florida and westward to the Mississippi Valley.

VI. GILA MONSTER, *Heloderma suspectum.*

A desert reptile inhabiting southern Arizona and New Mexico. This and an immediately related species of Mexico are the only known poisonous lizards of the New World. The fangs are in the lower jaw, and the venom is secreted in the salivary glands, which present a swollen appearance. While the poison is virulent, the bites of these creatures are seldom fatal to man.

REPRESENTATIVE POISONOUS REPTILES OF THE UNITED STATES.

The poisonous reptiles of North America may be popularly listed as representing five "kinds," thus: the Rattlesnake, Copperhead Snake, Water-moccasin, Coral-snake, and Gila Monster. The three former species belong to the long-fanged viperine serpents. The coral-snake belongs to a group containing the Old World cobras and their allies.

Creeping or crawling; repent; reptatory; reptile; specifically, of or pertaining to the *Reptantia*.

Reptantia† (rep-tan′shi-ạ), *n. pl.* [NL., neut. pl. of L. *reptan(t-)s*, ppr. of *reptare*, crawl: see *reptant*.] 1. In Illiger's classification (1811), the tenth order and also the thirtieth family of mammals, composed of the monotremes together with a certain tortoise (*Pamphractus*).—2. In *Mollusca*, those azygobranchiate gastropods which are adapted for creeping or crawling by the formation of the foot as a creeping-disk. All ordinary gastropods are *Reptantia*, the term being used in distinction from *Natantia* (which latter is a name of the *Heteropoda*). The *Reptantia* were divided into *Holochlamyda*, *Pneumonochlamyda*, and *Siphonochlamyda*.

reptation (rep-tā′shọn), *n.* [= F. *reptation*, < L. *reptatio(n-)*, a creeping, crawling, < *reptare*, pp. *reptatus*, creep, crawl: see *reptant*.] 1. The act of creeping or crawling on the belly, as a reptile does. *Owen.*—2. In *math.*, the motion of one plane figure around another, so as constantly to be tangent to the latter while preserving parallelism between different positions of its own lines; especially, such a motion of one figure round another precisely like it so that the longest diameter of one shall come into line with the shortest of the other. This motion was applied by John Bernoulli in 1705 to the rectification of curves. Let AB be a curve whose length is required; let this be reversed about its normal, giving the curve ABC, and let this be reversed about the line between its extremities, giving the spindle-shaped figure ABCD; let DEFG be a similar and equal figure turned through a right angle—then, if the first has a reptatory motion about the second, its center will describe a four-humped or quadrigibbous figure OPQRSTUV, with humps at P, R, T, V. Let this be placed in contact with a similar and equal figure so that a maximum and minimum diameter shall coincide, and receive a reptatory motion, then its center will describe an octogibbous or eight-humped figure. By a similar process, this will describe a sixteen-humped figure, etc. Each of these figures will have double the periphery of the preceding, and they will rapidly approximate toward circles. Hence, by finding the diameters of each, we approximate to the length of the original curve.

Reptation.

Reptilia[1] (rep-til′i-ạ), *n. pl.* [NL., pl. of LL. *reptile*, a reptile: see *reptile*.] In *zoöl.*: (*a*†) In Linnæus's system of classification (1766), the first order of the third class *Amphibia*, including turtles, lizards, and frogs. See *Amphibia*, 2 (*a*). [Disused.] (*b*) A class of cold-blooded oviparous or ovoviviparous vertebrated animals whose skin is covered with scales or scutes; the reptiles proper. There are two pairs or one pair of limbs, or none. The skull is monocondylian. The mandible articulates with the skull by a free or fixed quadrate bone. The heart has two auricles, generally not two completed ventricles; the ventricle gives rise to two arterial trunks, and the venous and arterial circulation are more or less mixed. Respiration is pulmonary, never branchial. No diaphragm is completed. There is a common cloaca of the digestive and urogenital systems, and usually two penes, sometimes one, seldom none. There are an amnion and an allantois. *Reptilia* thus defined were formerly associated with batrachians in a class *Amphibia*; but they are more nearly related to birds, and when brigaded therewith form their part of a superclass *Sauropsida*. The only living representatives of *Reptilia* are turtles or tortoises, crocodiles or alligators, lizards or saurians, and snakes or serpents, respectively constituting the four orders *Chelonia*, *Crocodilia*, *Lacertilia*, and *Ophidia*; and one living lizard, known as *Hatteria*, *Sphenodon*, or *Rhynchocephalus*, forming by itself an order *Rhynchocephalia*. In former times there were other orders of strange and huge reptiles, as the *Ichthyopterygia* or *Ichthyosauria*, the ichthyosaurs; *Anomodontia*; *Dinosauria*, by some ranked as a subclass and divided into several orders; *Ornithosauria* or *Pterosauria*, the pterodactyls; and *Plesiosauria* or *Sauropterygia*, the plesiosaurs. 2. A commonwealth; a government in which the executive power is vested in a person or persons chosen directly or indirectly by the body of citizens entitled to vote. It is distinguished from a monarchy on the one hand, and generally from a pure democracy on the other. In the latter case the mass of citizens meet and choose the executive, as is still the case in certain Swiss cantons. In a republic the executive is usually chosen indirectly, either by an electoral college as in the United States, or by the National Assembly as in France. Republics are oligarchic, as formerly Venice and Genoa, military, as ancient Rome, strongly centralized, as France, federal, as Switzerland, or, like the United States, may combine a strong central government with large individual powers for the several states in their particular affairs. See *democracy*.

S. hist.*, a name assumed during the administration of J. Q. Adams (1825–9) by that wing of the Democratic party which sympathized with him and his measures, as distinguished from the followers of Jackson. 3. That in which anything permanently rests or inheres.

4. A remaining or abiding where one's duties lie, or where one's occupation is properly carried on; *eccles.,* the presence of a bishop in his diocese, a canon in his cathedral or collegiate church, or a rector or an incumbent in his benefice: opposed to *non-residence.*

5. In *law:* (*a*) The place where a man's habitation is fixed without any present intention of removing it therefrom; domicile. (*b*) An established abode, fixed for a considerable time, whether with or without a present intention of ultimate removal. A man cannot fix an intentionally temporary domicile, for the intention that it be temporary makes it in law no domicile, though the abode may be sufficiently fixed to make it in law a residence in this sense. A man may have two residences, but only one can be his domicile. The bankruptcy law uses the term *residence* specifically, as contradistinguished from *domicile,* so as to free cases under it from the difficult and embarrassing presumptions and circumstances upon which the distinctions between *domicile* and *residence* rest. Residence is a fact easily ascertained, domicile a question difficult of proof. It is true that the two terms are often used as synonymous, but in law they have distinct meanings. (*Bump.*) See *resident.*

Residence is to be taken in its jural sense, so that a transient absence does not interrupt it.

In India: (*a*) Previous to the organization of the civil service, a chief of one of the commercial establishments of the East India Company. (*b*) Later, a representative of the viceroy at an important native court, as at Lucknow or Delhi.—7. The governor of a residency in the Dutch East Indies. =**Syn.** 1. (*b*) A chronic abscess in which the contents have been mostly absorbed.—**Residual air.** See *air*[1].—**Residual analysis**†, the calculus of differences. This is the old designation, employed by Landen, 1764.—**Residual calculus,**

the calculus of residuals or residues. See II.—**Residual charge**, a charge of electricity spontaneously acquired by coated glass, or any other coated dielectric arranged as a condenser after a discharge, apparently owing to the slow return to the surface of that part of the original charge which had penetrated within the dielectric, as in the Leyden jar. (*Faraday.*) In such cases there is said to be electric absorption. It is doubtless due to the fact that the solid dielectric does not immediately recover from the strain resulting from the electric stress. Also called *dielectric after-working.*—**Residual estate**, residuary estate.—**Residual figure**, in *geom.*, the figure remaining after subtracting a less from a greater.—**Residual magnetism.** See *magnetism.*—**Residual quantity**, in *alg.*, a binomial connected by the sign − (minus): thus, $a - b$, $a - \sqrt{b}$ are *residual quantities.*

II. *n.* 1. A remainder; especially, the remainder of an observed quantity, after subtracting so much as can be accounted for in a given way.—2. The integral of a function round a closed contour in the plane of complex quantity inclosing a value for which the function becomes infinite, this integral being divided by $2\pi i$. An earlier definition, amounting to the same thing, was the coefficient of x^{-1} in the development of the function a in a sum of two series, one according to ascending, the other according to descending powers of x. If the oval includes only one value for which the function becomes infinite, the residual is said to be taken for or with respect to that value. Also *residue.*

3. A system of points which, together with another system of points of which it is said to be the residual, makes up all the intersections of a given curve with a plane cubic curve.—**Integral residual** the residual obtained by extending the integration round a contour including several values of the variable for which the function becomes infinite.—**Total residual**, the residual obtained by integrating round a contour including all the values of the variable for which the function becomes infinite. Also called *principal residual.*

★**residuary** (rē-zid′ū-ā-ri), *a.* [= F. *résiduaire*, < NL. **residuarius*, < L. *residuum*, residue: see *residuum*, *residue.*] Of or pertaining to a residue or residuum; forming a residue, or part not dealt with: as, *residuary* estate (the portion of a testator's estate not devised specially).

'Tis enough to lose the legacy, or the *residuary* advantage of the estate left him by the deceased.

residuation (rē-zid-ū-ā′shon), *n.* [< *residuate* + *-ion.*] In *math.*, the act of finding the residual or integral round a pole divided by $2\pi i$; the process of finding residuals and co-residuals upon a cubic curve by linear constructions.—**Sign of residuation**, the sign $\int$ prefixed to the expression of a function to denote the residual. The rules for the use of this sign are not entirely consistent.

residue (rez′i-dū), *n.* [Early mod. E. also *residew*; < ME. *residue*, < OF. *residu*, F. *résidu* = Sp. Pg. It. *residuo*, < L. *residuum*, a remainder, neut. of *residuus*, remaining, < *residere*, remain, reside: see *reside.* Doublet of *residuum.*] 1. (*b*) That which remains of a testator's estate after payment of debts and particular legacies, and is undisposed of except it may be by a general clause or residuary legacy.—3. In the theory of numbers, the remainder after division, especially after division by a fixed modulus; in the integral calculus, the integral of a monodromic function taken round a pole or poles: same as *residual*, 2.—**Biquadratic residue**, the same as a *cubic residue*, except that it refers to a fourth power instead of to a cube. Thus, any fourth power of an integer divided by 5 gives as remainder either 0 or 1. These are, therefore, the *biquadratic residues* of 5.—**Cubic residue**, a number which, being added to a multiple of a number of which it is said to be a residue, gives a cube. Thus, every exact cube divided by 7 gives as remainder either 0, 1, or 6. These are, therefore, the *cubic residues* of 7.—**Method of residues.** See *method.*—**Quadratic residue.** See *quadratic.*—**Trigonal residue**, a number which, added to a multiple of another number of which it is said to be a residue, will give a trigonal number. Thus, 1, 3, 6, 10, 2, 8, are the *trigonal residues* of 13.=**Syn. 1.** *Rest*, etc. See *remainder.*

residuent (rē-zid′ū-ent), *n.* [< L. *residu(um)* + *-ent.*] In *chemical processes*, a by-product, or waste product, left after the removal or separation of a principal product.

New York Produce Exchange Report (1888–9), p. 279.

2. Specifically, in *law*, that part of an estate which is left after the payment of charges, debts, and particular bequests; more strictly, the part so left which is effectively disposed of by a residuary clause. Sometimes the subject of a particular bequest which proves ineffectual passes by law to the heir or next of kin, instead of falling into the residuum.

resign[1] (rē-zīn′), *v.* [< ME. *resignen*, *resynen*, < OF. *resiner*, *resigner*, F. *résigner* (> G. *resignieren* = Dan. *resignere* = Sw. *resignera*) = Pr. Sp. resin (rez′in), *n.* [Also *rosin,* q. v.; early mod. E. also *rasin;* < ME. *recyn, recyne,* also *rosyn, rosyne,* < OF. *resine* (also *rosine, rasine*), F. *résine* = Sp. Pg. It. *resina,* < L. *resina,* prob. < Gr. *ῥητίνη,* resin (of the pine).] 1. (*a*) A hardened secretion found in many species of plants, or a substance produced by exposure of the secretion to the air. It is allied to and probably derived from a volatile oil. The typical resins are oxidized hydrocarbons, amorphous, brittle, having a vitreous fracture, insoluble in water, and freely soluble in alcohol, ether, and volatile oils. They unite with alkalis to form soaps. They melt at a low heat, are non-volatile, and burn quickly with a smoky flame. The hardest resins are fossilized like amber and copal, but they show all gradations of hardness through oleoresins and balsams to essential oils. The *hard resins* are nearly inodorous, and contain little or no volatile oil; the *soft resins* owe their softness to the volatile oil associated with them. The common resin of commerce exudes in a semi-fluid state from several species of pine (in the United States, chiefly the long-leaved pine). From this the oil of turpentine is separated by distillation. Resins are largely used in the preparation of varnishes, and several are used in medicine. See *gum.* (*b*) The precipitate formed by treating a tincture with water.

Resistance is *passive,* as that of a fixed body which interrupts the passage of a moving body; or *active,* as in the exertion of force to stop, repel, or defeat progress or design.

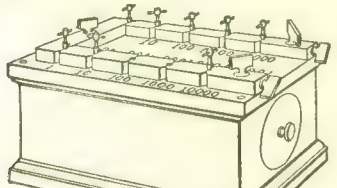
Shak., 2 Hen. IV., ii. 4. 109.

2. The force exerted by a fluid or other medium to retard the motion of a body through it; more generally, any force which always acts in a direction opposite to the residual velocity, or to any component of it: as, *resistance* to shearing. In a phrase like this, *resistance* may be defined as a stress produced by a strain, and tending to restoration of figure. But the resistance is not necessarily elastic—that is, it may cease, and as resistance does cease, when the velocity vanishes. In the older dynamical treatises, resistance is always considered as a function of the velocity, except in the case of friction, which does not vary with the velocity, or at least not much. In modern hydrodynamics the viscosity is taken into account, and produces a kind of resistance partly proportional to the velocity and partly to the acceleration. The theory of resistance still remains imperfect.

Energy, which is force acting, does work in overcoming *Resistance,* which is force acted on and reacting.
G. H. Lewes, Probs. of Life and Mind, II. v. § 5.



3. In *elect.,* that property of a conductor in virtue of which the passage of a current through it is accompanied by a dissipation of energy; the transformation of electric energy into heat. It is one of the two elements upon which the strength of an electric current depends when the flow is steady; the other is electromotive force, and the relation between them is generally expressed by the equation $I = E/R$, which is Ohm's law. *Resistance* may therefore be defined as the ratio of the electromotive force to the current strength ($R = E/I$), the flow being assumed to be steady. With alternating currents, the self-induction acts like a resistance, in consuming electromotive force, without, however, being accompanied by a dissipation of energy. This apparent resistance of self-induction is called *reactance,* and is proportional to the rapidity of alternation, and the total apparent resistance for alternating currents is called *impedance.* It is greater than the resistance for a steady flow, which then is named *ohmic resistance.* In general, resistance is proportional to the length of the conductor and inversely proportional to its cross-section. It also varies with the temperature of the conductor, the nature of the material of which it is composed, the stress

to which it is subjected, and in some instances with other physical conditions. It is the reciprocal of *conductance*. See *ohm*. The designation *resistance* is also applied to coils of wire or other material devices which are introduced into electric circuits on account of the resistance which they offer to the passage of the current. The resistance of a conductor may be measured by Wheatstone's bridge. This is a device for the accurate comparison of electric resistances, invented by Christie and brought into notice by Wheatstone. It consists essentially of a complex circuit of six conductors, arranged as shown in the cut. A current from the battery B enters at the junction of *a* and *c*, and, after dividing into parts depending on the relative resistances of the branches *a*, *b*, *c*, and *d*, returns to the battery through the junction of *b* and *d*. G is a galvanometer joined to the junctions *a b* and *c d*. When the relative resistances are such that $a : b :: c : d$, no current will flow through the galvanometer. If *a* and *b* are comparable and adjustable resistances, it is only necessary to establish this condition in order to know the ratio of *c* to *d*. Many modifications of the bridge have been devised.—**Center of resistance.** See *center*[1].—**Conduction resistance,** the resistance offered by a conductor to an electric current.—**Contact resistance.** See *contact*.—**Curve of elastic resistance.** See *curve*.—**Living resistance,** the work required to produce a sudden strain of a body, especially a sudden elongation of a solid.—**Magnetic resistance,** the reciprocal of magnetic conductance or permeance. The magnetic flux, or total number of magnetic lines of force passing through a cross-section of any magnetic circuit, may be given in an expression analogous to that giving the strength of an electric current in terms of the electromotive force and resistance. The denominator of the fraction represents the magnetic resistance, sometimes called *reluctance*.—**Passive resistance,** a friction or similar force opposing the motion of a machine.—**Principle of least resistance,** the principle that when a structure is in equilibrium the passive forces, or stresses occasioned by minute strains, are the least that are capable of balancing the active forces, or those which are independent of the strains.—**Solid of least resistance,** in *mech.*, the solid whose figure is such that in its motion through a fluid it sustains less resistance than any other having the same length and base, or, on the other hand, being stationary in a current of fluid, offers the least interruption to the progress of that fluid. In the former case it has been considered the best form for the stem of a ship; in the latter, the proper form for the pier of a bridge. The problem of finding the solid of least resistance was first proposed and solved by Newton, but only for hypothetical conditions extremely remote from those of nature.—**Specific resistance,** the resistance offered by a conductor of any given material the length of which is one centimeter and the cross-section one square centimeter.—**Transition resistance,** the resistance to an electric current in electrolysis caused by the presence of the ions at the electrodes.=**Syn. 1.** Hindrance, antagonism, check. In many wind-instruments, like the flute, and the flue-pipes of an organ, the pitch of the tone is almost wholly determined by the shape and size of the resonant cavity. In the voice, the quality of both song and speech and the distinctions between the various articulate sounds are largely governed by the resonance of the cavities of the pharynx, mouth, and nose. Resonance occurs not only in sound, but also in the case of vibrations affecting the ether, such as light-vibrations, electromagnetic vibrations, etc.

The act of breathing again or resuming life.

Till the day
Appear of *respiration* to the just,
And vengeance to the wicked.
Milton, P. L., xii. 540.

2. The inspiration and expiration of air.—3. That function by which there takes place an absorption of oxygen from the surrounding medium into the blood with a corresponding excretion of carbon dioxid. This is accomplished in the higher animal forms chiefly by the lungs and skin; the gills or branchiæ of aquatic animals and the tracheæ of insects perform the same function. In unicellular organisms these changes take place in the protoplasm of the cell itself. The number of respirations in the human adult is from 16 to 24 per minute. About 500 centimeters or one sixth of the volume of the air in the lungs is changed at each respiration, giving a daily income of about 744 grams of oxygen and an expenditure of 900 grains of carbon dioxid. Inspiration is slightly shorter than expiration.

Ev'ry breath, by *respiration* strong
Forc'd downward.
Cowper, Task, iv. 348.

4. In *physiological bot.*, a process consisting in the absorption by plants of oxygen from the air, the oxidation of assimilated products, and the release of carbon dioxid and watery vapor. It is the opposite of *assimilation*, in which carbon dioxid (carbonic acid) is absorbed and oxygen given off—contrasted also as being the waste process in the plant economy, a part of the potential energy of a higher compound being converted into kinetic energy, supporting the activities of the plant, the resulting compound of lower potential being excreted. Respiration takes place in all active cells both by day and by night; assimilation only by daylight (then overshadowing the other process) and in cells containing chlorophyl.

5. The respiratory murmur.—6†. A breathing-spell; an interval.

Some meet *respiration* of a more full trial and enquiry into each others' condition.
Bp. Hall, Cases of Conscience, iv. 6.

Abdominal respiration. See *abdominal*.—**Amphoric respiration,** respiratory murmur with musical intonation, such as might be produced by blowing across the mouth of a bottle. It occurs in some cases of pneumothorax and with some phthisical cavities.—**Artificial respiration,** respiration induced by artificial means. It is required in cases of drowning, the excessive inhalation of chloroform or of noxious gases, etc. In the case of a person apparently drowned, or in an asphyxiated condition, the following treatment has been recommended. After clearing the mouth and throat, the patient should be laid on his back on a plane inclined a little from the feet upward; the shoulders gently raised by a firm cushion placed under them; the tongue brought forward so as to project from the side of the mouth, and kept in that position by an elastic band or string tied under the chin. Remove all tight clothing from neck and chest. The arms should then be grasped just above the elbows, raised till they nearly meet above the head, and kept stretched upward for two seconds: this action imitates inspiration. The arms are then turned down and firmly pressed for two seconds against the sides of the chest, thus imitating a deep expiration. These two sets of movements should be perseveringly repeated at the rate of fifteen times in a minute. As soon as a spontaneous effort to breathe is perceived, cease the movements and induce circulation and warmth.—**Branchial respiration.** See *branchial*.—**Bronchial respiration,** respiration such as is heard immediately over bronchi, or over the trachea. The inspiratory sound is high in pitch and tubular; the expiratory sound is higher, tubular, and prolonged. It is heard in disease over consolidated lungs. Also called *tubular respiration*.—**Bronchocavernous respiration,** respiration intermediate in character between bronchial and cavernous respiration.—**Bronchovesicular respiration,** respiration intermediate in character between bronchial and vesicular respiration.—**Cavernous respiration.** See *cavernous*.—**Center of respiration,** the nervous center which regulates respiration. It is automatic in action, but is guided by incoming influences from the vagus, the skin, and elsewhere. The main center is limited in extent, and situated in the floor of the fourth ventricle, near the point of the calamus.—**Cerebral respiration,** shallow, quick, irregular, more or less sighing respiration, sometimes resulting from cerebral disease in children.—**Cheyne-Stokes respiration,** a rhythmic form of respiration described by Cheyne in 1818 and by Stokes in 1846. It consists of a series of cycles in every one of which the respirations pass gradually from feeble and shallow to forcible and deep, and then back to feeble again. A pause follows, and then the next cycle begins with a feeble inspiration. This symptom has been found associated with cardiac and brain lesions.—**Cogged** or **cog-wheel respiration.** Same as *interrupted respiration*.—**Costal respiration,** respiration in which the costal movements predominate over the diaphragmatic.—**Cutaneous respiration,** gaseous absorption and excretion by the skin.—**Diaphragmatic respiration.** Same as *abdominal respiration* (which see, under *abdominal*).—**Divided respiration,** respiration in which inspiration is separated from expiration by a well-marked interval.—**Facial respiration,** respiratory movements of the face, as of the alæ nasi.—**Harsh respiration.** Same as *rude respiration*.—**Indeterminate respiration.** Same as *bronchovesicular respiration*, especially its more vesicular grades.—**Interrupted respiration,** respiration in which the inspiratory, sometimes the expiratory, sound is broken into two or more parts. Also called *jerking*, *wavy*, and *cogged* or *cog-wheel respiration*.—**Jerking respiration.** Same as *interrupted respiration*.—**Laryngeal respiration,** laryngeal respiratory movements.—**Metamorphosing respiration,** respiration in which the first part of the inspiratory sound is tubular and the last part cavernous.—**Organs of respiration,** any parts of the body by means of which constituents of the blood are interchanged with those of air or water. In the higher vertebrates, all of which are air-breathers, such organs are internal, and of complex lobulated structure, called *lungs*. (See *lung*.) In lower vertebrates and many invertebrates respiration is effected by breathing water, and such organs are usually called *gills* or *branchiæ*. Most invertebrates, however (as nearly all the immense class of insects), breathe air by various contrivances for its admission to the body, generally of tubular or laminated structure, which may open by pores or spiracles on almost any part of the body. The organs of mollusks are extremely variable in form and position; they are commonly called *branchiæ* or *gills*, technically *ctenidia*. Some gastropods, called *pulmonate*, are air-breathers. Arachnidans are distinguished as *pulmonate* and *tracheate*, according to the laminate (or saccular) or the simply tubular character of their organs of respiration. The character of the lungs as offsets of the alimentary canal is somewhat peculiar to the higher vertebrates—being represented in the lower, as fishes, only by an air-bladder, if at all; and the various organs of respiration of lower animals are only analogous or functionally representative, not homologous or morphologically representative, of such lungs. (See *pneogaster*.) In birds the organs are distributed in most parts of the body, even in the interior of bones. (See *pneumatocyst*.) In embryos the allantois is an organ of respiration, as well as of digestion and circulation. See cuts under *Branchiostoma*, *gill*, and *Mya*.—**Puerile respiration.** See *puerile*.—**Rough respiration.** Same as *rude respiration*.—**Rude respiration,** a form of bronchovesicular respiration, the sounds being harsh.—**Supplementary respiration,** respiration with increased vesicular murmur, as heard over normal parts of the lungs when some other part of them is incapacitated, as from pneumonia or pleurisy.—**Thoracic respiration.** Same as *costal respiration*.—**Tubular respiration.** Same as *bronchial respiration*.—**Vesiculocavernous respiration,** respiration intermediate in character between vesicular and cavernous respiration.

It is mostly used to exclude the passage into the lungs of cold air, smoke, dust, and other noxious substances, especially by persons having delicate chests, by firemen, cutlers, grinders, and the like, and by divers in operations under water. Respirators for persons with weak lungs have several plies of fine gauze made of highly heat-conducting metal, which warms the air as it passes through. See *aërophore*.

With regard to the legal use of the word, two conceptions are often confused—namely, that of the potential condition of being bound to answer or respond in case a wrong should occur, and that of the actual condition of being bound to respond because a wrong has occurred. For the first of these *responsible* is properly used, and for the second *liable*.

This hook also is called *rest*. A similar hook was sometimes arranged so far at the side, and so projecting, as to receive the lance itself; but, this form being inconvenient, the projecting hook was arranged with a hinge. In the justs of the fifteenth and sixteenth centuries the heavy lance was found to require a counterpoise, and the rest was made double, the hook projecting sidewise, and a long tongue or bar projecting backward under the arm with a sort of spiral twist at the end to prevent the butt of the lance from rising, so that the lance was held firmly, and required from the juster only the exertion of directing its point.

The duration of a rest, as of a note, may be extended one half by a dot, as 𝄽. (= 𝄽 𝄾), or indefinitely by a hold, 𝄐. The semibreve rest is often used as a measure-rest, whatever may be the rhythmic signature (as *a* below); similarly, the two-measure rest is like *b*, the three-measure rest like

F. Clarke*, Orthodoxy, its Truths and Errors, xii. § 6. (3) The doctrine of Swedenborg, that every man is possessed of two bodies, a natural and a spiritual, the latter within the former, and that at death the natural body is laid aside and the spiritual body rises at once from the death of the natural, resurrection thus taking place for every one immediately upon and simultaneously with death. retina (ret′i-nä), *n.* [= OF. *retine*, *rectine*, F. *rétine* = Sp. Pg. It. *retina*, < NL. *retina*, retina: so called because resembling fine network, < L. *rete*, a net: see *rete*.] The innermost and chiefly nervous coat of the posterior part of the eyeball, between the choroid coat and the vitreous humor. It extends from the entrance into the eyeball of the optic nerve toward the crystalline lens, terminating in the ora serrata. A modified division of the retinal structure is, however, continued forward as the pars ciliaris retinæ. The retina consists of a delicate and complex expansion and modification of the optic nerve, supported by a network of connective tissue. It may be divided into ten layers: (1) internally, next the hyaloid membrane of the vitreous humor, the internal limiting membrane, formed of the expanded bases of the fibers of Müller; (2) the fibers of the optic nerve; (3) layer of ganglion-cells; (4) internal molecular or granular layer; (5) inner nuclear layer; (6) external molecular or granular layer; (7) external nuclear layer; (8) external limiting membrane, which is connected with the ends of Müller's fibers; (9) layer of rods and cones, or bacillary layer; (10) pigmentary layer. In the center of the back part of the retina, near the line of the optic axis, is the macula lutea, the most sensitive part of the retina; and in the center of the macula is a depression, the fovea centralis, in which the rods are absent. The color of the macula is due to a yellow pigment. About one tenth of an inch internally to the fovea is the point of entrance of the optic nerve with its central artery; the retina is incomplete at this point, and constitutes the "blind spot." The nerve-fibers have been estimated to number 400,000 broad and as many narrow fibers, and for each fiber there are 7 cones, 100 rods, and 7 pigment-cells. The retina serves the purpose of vision in being the organ through or by means of which vibrations of luminiferous ether excite the optic nerve to its appropriate activity. See *eye*[1].—**Central artery and vein of retina.** See *central.*—**Coarctate retina,** a funnel-shaped condition of the retina, due to the accumulation of fluid between the retina and the choroid.—**Epilepsy of the retina.** See *epilepsy.*—**Pigmentary layer of the retina.** See *pigmentary.*—**Rod-and-cone layer of the retina,** a layer composed of minute elongated cylindrical and flask-shaped elements arranged vertically to the pigmentary layer of the retina, and parallel to one another. Also called *columnar layer, bacillar layer, bacillary layer, stratum bacillosum, stratum cylindrorum, Jacob's membrane, Jacobian membrane.*

Retribution theory, the theory that the condition of the soul after death depends upon a judicial award of rewards and punishments based upon the conduct pursued and the character developed in this life. It is distinguished from the theory that the future life is (*a*) simply a continuance of the present (continuance theory); (*b*) a life of gradual development by means of discipline (purgatory), or future redemptive influences (future probation).

On the whole, however, in the religions of the lower range of culture, unless where they may have been affected by contact with higher religions, the destiny of the soul after death seems comparatively seldom to turn on a judicial system of reward and punishment. Such difference as they make between the future conditions of different classes of souls seems often to belong to a remarkable intermediate doctrine, standing between the earlier continuance theory and the *retribution theory.*

There is a wide difference of opinion as to the interpretation and significance of this book. The schools of interpretation are of three principal kinds. The first school, that of the preterists, embraces those who hold that the whole or by far the greater part of the prophecy of this book has been fulfilled; the second is that of the historical interpreters, who hold that the prophecy embraces the whole history of the church and its foes, from the first century to the end of the world; the third view is that of the futurists, who maintain that the prophecy, with perhaps the exception of the first three chapters, relates entirely to events which are to take place at or near to the second coming of the Lord. =**Syn.** 1. *Revenge*, *Vengeance*, *Retribution*, *Retaliation*, and *Reprisal* agree in expressing the visiting of evil upon others in return for their misdeeds. *Revenge* is the carrying out of a bitter desire to injure an enemy for a wrong done to one's self or to those who seem a part of one's self, and is a purely personal feeling. It generally has reference to one's equals or superiors, and the malignant feeling is all the more bitter when it cannot be gratified. *Vengeance* has an earlier and a later use. In its earlier use it may arise from no personal feeling, but may be visited upon a person for another's wrong as well as for his own. In the Scripture it means retribution with indignation, as in Rom. xii. 19: "*Vengeance* is mine; I will repay, saith the Lord," where it is a reservation for Jehovah of the offices of distributive and retributive justice. In its later use it involves the idea of wrathful retribution, whether just, unjust, or excessive; it is often a furious revenge: hence there is a general tendency to turn to other words to express just retribution, especially as an act of God. *Retribution* bears more in mind the amount of the wrong done, viewing it as a sort of loan whose equivalent is in some way paid back. Any evil result befalling the perpetrator of a bad deed in consequence of that deed is said to be a *retribution*, whether occurring by human intention or not; personal agency is not prominent in the idea of *retribution*. *Retaliation* combines the notion of equivalent return, which is found in *retribution*, with a distinctly personal agency and intention; sometimes, unlike the preceding words, it has a light sense for good-humored teasing or banter. *Reprisal* is an act of retaliation in war, its essential point being the capture of something in return or as indemnification for pecuniary damage from the other side. The word has also a looser figurative meaning, amounting essentially to retaliation of any sort. See *avenge*, *requital*, and the definition of *retorsion*.

The observation of such a bright-line spectrum, first made by Professor C. A. Young in 1870, and since repeated more or less completely by several eclipse observers, led to the hypothesis. Its founder was H. J. Rose, with whom were joined Arthur Percival, Hurrel Froude, and William Palmer, and, a little later, John Henry Newman (originally an Evangelical) and John Keble, the publication of whose "Christian Year" in 1827 has been regarded as an important precursor of the movement. She was probably the very last person in town who still kept the time-honored spinning-wheel in constant *revolution*.
Hawthorne, Seven Gables, v.

2. The act of moving completely around a circular or oval course, independently of any rotation. In a revolution without rotation, every part of the body moves by an equal amount, while in rotation the motions of the different parts are proportional to their distances from the axis. But revolutions and rotations may be combined. Thus, the planets perform *revolutions* round the sun, and at the same time *rotations* about their own axes. The moon performs a *rotation* on its axis in precisely the same time in which it performs a *revolution* round the earth, to which it consequently always turns the same side.

Such restless *revolution* day by day.

Hence—**4.** A recurrent period or moment in time. [Rare.]

The term *Revolution*, in English history, is applied distinctively to the convulsion by which James II. was driven from the throne in 1688. In American history it is applied to the war of independence. See below. [In this sense the word is sometimes used adjectively.]

The elections . . . generally fell upon men of *revolution* principles. *Smollett*, Hist. Eng., i. 6.

The *revolution*, as it is called, produced no other changes than those which were necessarily caused by the declaration of independence. *Calhoun*, Works, I. 189.

9. The winding or turning of a spiral about its axis, as a spiral of a shell about the columella; one of the coils or whorls thus produced; a volution; a turn.—**American Revolution**, the series of movements by which the thirteen American colonies of Great Britain revolted against the mother country, and asserted and maintained their independence. Hostilities began in 1775, independence was declared in 1776, and the help of France was formally secured in 1778. The war was practically ended by the surrender of the chief British army at Yorktown in 1781, and the independence of the United States was recognized by treaty of peace in 1783.—**Anomalistic revolution.** See *anomalistic*.—**English Revolution**, the movements by which James II. was forced to leave England, and a purer constitutional government was secured through the aid of William of Orange, who landed with an Anglo-Dutch army in November, 1688. In 1689 William and Mary were proclaimed constitutional sovereigns, and Parliament passed the Bill of Rights.—**French Revolution**, the series of movements which brought about the downfall of the old absolute monarchy in France, the establishment of the republic, and the abolition of many abuses. The States General assembled in May, 1789, and the Third Estate at once took the lead. The Bastille was stormed by the people, and in the same year the Constituent Assembly overthrew feudal privileges and transferred ecclesiastical property to the state. Abolition of titles and of right of primogeniture, and other reforms, were effected in 1790. The next year a constitution was adopted and the Constituent was succeeded by the Legislative Assembly. In 1792 a coalition of nations was formed against France, the royal family was imprisoned, and in September the Convention replaced the Legislative Assembly and proclaimed the republic. Louis XVI. was executed in 1793, and the Reign of Terror followed in 1793–4; royalist risings were suppressed, and the foreign wars successfully prosecuted. The revolutionary period may be regarded as ending with the establishment of the Directory in 1795, or as extending to the founding of the Consulate in 1799, or even later. Other French revolutions in 1830, 1848, and 1870 resulted respectively in the overthrow of the Bourbon monarchy of the Restoration, of the monarchy of Louis Philippe, and of the Second Empire.—**Pole of revolution.** See *pole*².—**Revolution-indicator.** Same as *opercameter*.—**Solid of revolution**, a solid containing all the points traversed by a plane figure in making a revolution round an axis in its plane, and containing no others. The *ellipsoid*, *paraboloid*, *hyperboloid*, etc., *of revolution* are examples.=**Syn. 6.** See *insurrection*.

ly—(*a*) A revolving firearm, especially a pistol, having a revolving barrel provided with a number of bores (as in earlier styles of the weapon), or (as in modern forms) a single barrel with a revolving cylinder at its base, provided with a number of chambers. When the barrel or cylinder revolves on its longitudinal axis, the several bores or chambers are brought in succession into relation with firing-mechanism for successive and rapid firing. In the modern forms of the arm the chambers of the cylinder are, by such revolution, brought successively into line with the bore in the barrel, which is also the firing position. In this position each chamber respectively forms a continuation of the bore in the barrel. Six is the common number of chambers. The most vital distinction between early and modern revolving firearms is that the barrels of the former were directly revolved by the hand; while in the latter the revolving-mechanism is connected with the firing-mechanism, the cocking of which automatically revolves the cylinder. Metal cartridges with conical bullets are used in all modern revolvers, the loading being done at the breech. Some are self-cocking—that is, are cocked by pulling the trigger which also discharges them. Some, by peculiar mechanism (though, for general use, they may be cocked in the ordinary way for taking deliberate aim), are by a quick adjustment changed into self-cocking pistols for more rapid firing in emergencies where accurate aim is of subordinate importance. Colonel Colt of the United States was the first to produce a really serviceable and valuable revolving arm, though the principle was known in the earlier part of the sixteenth century. (*b*) A revolving cannon.—**3.** A revolving horse-rake.

The heat is supplied by a Siemens regenerative gas-furnace, or by a coal-furnace, and the hot flame circulates longitudinally through the cylinder into a smoke-stack or chimney. The charging is done through a hole in the side of the cylinder, and the crude soda, rolled into balls by the motion of the cylinder, is discharged through the same opening.—**Revolving pistol.** Same as *revolver.*—**Revolving press.** See *press*[1].—**Revolving storm,** a cyclone.

Rhabdocœla (rab-dō-sē′lą), *n. pl.* [NL., < Gr. *ῥάβδος*, a rod, + *κοίλος*, hollow.] A prime division of turbellarian worms, forming a suborder of *Turbellaria*, contrasted with *Dendrocœla* (which see), containing small forms whose intestine, when present, is straight and simple. The body is cylindric (as compared with other flatworms), but more or less flattened; the sexual organs are usually hermaphrodite; there is no anus (see *Aprocta*), but a mouth, the position of which varies extremely in different genera, and usually a protrusile pharynx or buccal proboscis. In most forms the alimentary canal is distinct; in others (see *Acœla*) it is not fairly differentiated from the general digestive parenchyma. There are numerous forms of this group, mostly inhabiting fresh water, though some are marine. They live on the juices of small worms, crustaceans, and insects, which they suck after enveloping their prey in a sort of mucus secreted by the skin and containing rhabdites. (See *rhabdite*, 2.) The group is divided, mainly upon the character of the intestine, into three sections: (1) *Acœla*, without differentiated intestine, represented by the family *Convolutidæ*; (2) *Rhabdocœla* proper, with definite intestinal tract, a nervous system and excretory organs present, compact male and female generative glands, complicated pharynx, and generally no otoliths—embracing numerous forms of several different families, both of fresh and salt water; (3) *Allœocœla*, resembling (2), but with otoliths, represented by one family, *Monotidæ*. Another division, based mainly upon the position or other character of the mouth, is directly into a number of families, as *Convolutidæ*, *Opisthomidæ*, *Derostomidæ*, *Mesostomidæ*, *Prostomidæ*, and *Microstomidæ*. Also called *Rhabdocœlida*.

There are about 70 species, natives of warm and temperate regions, frequent in Europe, Asia, and America, rare in the tropics. They bear alternate petioled and feather-veined leaves, which are either entire or toothed, deciduous or evergreen, and are furnished with small deciduous stipules. The flowers are in axillary racemes or cymes, and are commonly dicœcious in the typical section, but not so in the principal American species (the genus *Frangula* of Brongniart), which also differ in their unfurrowed seeds and flat fleshy seed-leaves. It is used as a hedge-plant. Its bark is medicinal, like that of *R. Frangula*; its black berries afford a now nearly disused cathartic, and with

Sometimes they cast dice on a table on which verses were written, and that on which the die lodged contained the prediction. A third manner was by opening a book, and pitching on some verse at first sight. E. *rhetorick*, *rethoryck*; < ME. *retorike*, *rethoryke*, *retoryke*, *retoryk* (also *rethorice*, after L. *rhetorice*), < OF. *rhetorique*, *rectorique*, F. *rhétorique* = Pr. *rethorica* = Sp. *retórica* = Pg. *rhetorica* = It. *retorica*, *rettorica*, < L. *rhetorica* (sc. *ars*), also *rhetorice*, < Gr. *ῥητορική* (sc. *τέχνη*), the rhetorical art, fem. of *ῥητορικός* (> L. *rhetoricus*), of or pertaining to a speaker or orator, rhetorical, < *ῥήτωρ*, a speaker, orator: see *rhetor.*] 1. The art of discourse; the art of using language so as to influence others. Rhetoric is that art which consists in a systematic use of the technical means of influencing the minds, imaginations, emotions, and actions of others by the use of language. Primarily, it is the art of oratory, with inclusion of both composition and delivery; secondarily, it also includes written composition and recitation. It is also used in narrower senses, so as to present the idea of composition alone, or the idea of oratorical delivery (elocution) alone. Etymologically, rhetoric is the art, or rather the technics (*τέχνη*, somewhat different in scope from our *art*), of the rhetor—that is, either the popular (political) orator or the judicial and professional rhetor. Accordingly, ancient writers regarded it mainly as the art of persuasion, and something of this view almost always attaches to the word even in modern use, so that it appears to be more or less inappropriate to use *rhetoric* of mere scientific, didactic, or expository composition. The element of persuasion, or at least of influence of thought, belongs, however, to such composition also in so far as accurate and well-arranged statement of views leads to their adoption or rejection, the very object of instruction involving this. On the other hand, poetry and epidictic oratory chiefly address the imagination and emotions, while the most important branches of oratory (deliberative and judicial oratory) appeal especially to the mind and emotions with a view to influencing immediate action. The theory or science underlying the art of rhetoric, and sometimes called by the same name, is essentially a creation of the ancient Greeks. Rhetoric was cultivated on its more practical side first of all by the earlier rhetors (so-called "sophists") and orators (Empedocles—considered the inventor of rhetoric—Gorgias, Isocrates, etc.), many of whom wrote practical treatises (*τέχναι*) on the art. The philosophers, on the other hand, among them Aristotle, treated the subject from the theoretical side. The system of rhetoric which finally became established, and has never been superseded, though largely mutilated and misunderstood in medieval and modern times, is that founded upon the system of the Stoic philosophers by the practical rhetorician Hermagoras (about 60 B. C.). Its most important extant representatives are Hermogenes (about A. D. 165) among the Greeks, and Quintilian (about A. D. 95) among the Latins. This theory recognizes three great divisions of oratory. (See *oratory.*) The art of rhetoric was divided into five parts: invention, disposition, elocution (not in the modern sense, but comprising diction and style), memory (mnemonics), and action (delivery, including the modern elocution).

The word is used with a certain and unfortunate freedom in application to joint pains of various origins and anatomical forms.—**Acute articular rheumatism,** an acute febrile disease, with pain and inflammation of the joints as the prominent symptom. It is to be separated as of distinct, possibly bacterial, origin from joint affections caused by gout, plumbism, scarlatina, gonorrhea, septicemia, tuberculosis, or syphilis. It often begins suddenly; a number of joints are usually attacked one after the other; the fever is irregular; there is apt to be profuse sweating; endocarditis, pericarditis, pleuritis, sudamina, erythema nodosum, hyperpyrexia, and delirium are more or less frequent features of the cases. Its duration is from one to six weeks or more. It is most frequent between 15 and 35, but may occur in the first year of life or after 50. One attack does not protect, but, as in pneumonia and erysipelas, is often succeeded by others. It almost always issues in recovery, but frequently leaves permanent cardiac lesions. [NL., < Gr. *ῥίς* (*ῥιν-*), nose, + *ἐγκέφαλος*, brain: see *encephalon.*] The olfactory lobe of the brain; the foremost one of the several morphological segments of the encephalon, preceding the prosencephalon. In the lower vertebrates the rhinencephalon is relatively large, and evidently a distinct part of the brain. In the higher it gradually diminishes in size, becoming relatively very small, and apparently a mere outgrowth of the cerebrum. Thus, in man the rhinencephalon is reduced to the so-called pair of olfactory nerves, from their roots in the cerebrum to the olfactory bulbs whence are given off the numerous filaments, the proper olfactory nerves, which pierce the cribriform plate of the ethmoid, and ramify in the nose. The rhinencephalon, like other encephalic segments, is paired or double—that is, consists of right and left halves. It is primitively hollow, or has its proper ventricle, which, however, is entirely obliterated in the adults of the higher vertebrates. This hollow is a prolongation of the system of cavities common to the other encephalic segments, and known as the *rhinocœle.* Also *rhinencephal.* See cuts under *Petromyzontidæ*, *Rana*, *brain* (cut 2), and *encephalon.*

A large pachydermatous perissodactyl mammal with a horn on the nose; any member of the genus *Rhinoceros* or family *Rhinocerotidæ*. There are several living as well as many fossil species. They are huge ungainly quadrupeds, having an extremely thick and tough or hard skin, thrown into various buckler-like plates and folds. The legs are short, stout, and clumsy, with odd-toed feet, whose three digits are incased in separate hoofs. The tail is short; the ears are high and rather large; the head is very large and unshapely, supported upon a thick stocky neck; the muzzle is blunt, and the upper lip freely movable. The head is especially long in the nasal region, and there are usually one or two massive upright horns, without any bony core, the substance of the horn being epidermal only. When two horns are present they are one behind the other in the median line, and the hinder one rests over the frontal bone, the front one being in any case borne upon the nasal bones. Rhinoceroses live mainly in marshy places, in thick or rank vegetation, and subsist entirely upon vegetable food. The living species are now confined to the warmer parts of Africa and Asia, and are hairless or nearly so; but these animals formerly had a much more extensive range, not only in the Old World, but also in America. The best-known of the extinct species is *R. tichorhinus*, the woolly rhinoceros, which formerly ranged over Europe, including the British Isles. Of the existing one-horned

One-horned Rhinoceros (*Rhinoceros unicornis*).

species are the Indian rhinoceros, *R. indicus* or *R. unicornis*, which inhabits the warmer parts of Asia, attains a height of 5 feet, and has the horn short and stout; the Javan rhinoceros, *R. sondaicus*, or *R. javanus*, distinct from the Indian species, inhabiting Java, the Malay peninsula, etc.; the hairy-eared rhinoceros, *R. lasiotis*; and the African kobaoba, *R. simus*. The two-horned species include the Sumatran or Malaccan rhinoceros, *R. sumatrensis*; and the African keitloa, *R. keitloa* or *bicornis*. See also cut under *Perissodactyla*.

The common rhinoceros-beetle of the United States, *Dynastes tityus*, the largest of the North American beetles, has two large horns directed forward, one arising from the thorax and one from the head, in the male beetle only. The general color is greenish-gray with black markings and between this form and a uniform brown there are many gradations. The larva feeds in decaying stumps and logs. Both beetle and larva have a peculiarly disagreeable odor, which, when they are present in any number, becomes insupportable. *D. hercules* of South America is another rhinoceros-beetle, specifically called the *Hercules-beetle*, whose prothoracic horn is immensely long. See also cut under *Hercules-beetle*.

The neck is comparatively abbreviated. The molar crowns are traversed by continuous ridges, more or less well defined, the upper ones having a continuous outer wall without complete transverse crests; the incisors are reduced in number or entirely suppressed. The basioccipital is comparatively broad behind and narrow forward; the tympanic and periotic bones are ankylosed and wedged in between the squamosal, exoccipital, and other contiguous bones. The only living genus is *Rhinoceros*, from which *Rhinaster* and *Atelodus* are sometimes separated. There are several extinct genera, as *Metamynodon*, *Aceratherium*, and *Diceratherium*. The family is one of only three which now represent the once numerous and diversified suborder *Perissodactyla*, the other two being the *Tapiridæ* or tapirs and the *Equidæ* or horses. In some plants rhizomania is an indication that there is some defect in the true root, in consequence of which it cannot supply sufficient nourishment to the plant. In such cases rhizomania is an effort of nature to supply the deficiency. This is the case in common laurel, in which plant rhizomania generally forebodes death. The phenomenon is also frequently seen in apple-trees, from the stems of which bundles of roots are sent out; these, absorbing moisture and finally decaying, are a cause of canker on the tree.

Three species recognized by modern authors are frequent on muddy or coral shores in the tropics, there forming dense and almost impassable jungles known as mangrove-swamps. They are trees with thick cylindrical and scarred branchlets, bearing opposite thick and smooth coriaceous leaves, which are ovate or elliptical and entire. Their large rigid flowers are borne in axillary clusters, followed by a nut-like one-seeded fruit. The seed is remarkable for germinating while yet in the long-persistent fruit. It contains a large embryo with a very long club-shaped radicle, which soon pierces the point of the hard pericarp and lengthens till it reaches the mud, or becomes a foot long before falling. The mangrove is also remarkable for spreading by aërial roots. The ordinary species is *R. Mangle,* which reaches to semitropical Florida, the delta of the Mississippi, and Texas. See *mangrove,* 1.

It includes about 52 species in 17 genera and 3 tribes, all tropical, and most of them forming dense and malarious jungles about river-mouths and along shores. They are usually extremely smooth, with round and nodose branchlets, and opposite thick and rigid leaves, which are commonly entire and have elongated and very caducous intrapetiolar stipules. They bear axillary cymes, panicles, spikes, or racemes of rather inconspicuous flowers.

In Dujardin's system of classification (1841), the third family of "diversiform infusorians without visible locomotory appendages"—that is, without permanent appendages, as cilia or flagella. This is the original meaning of the word, since much extended. Dujardin included in his *Rhizopoda* the 8 genera *Arcella, Difflugia, Trinema, Euglypha, Gromia, Miliola, Cristellaria,* and *Vorticella.*

2. The lowest class of *Protozoa,* composed of simple or multiple animalcules without definite or permanent distinction of external parts, and provided with diversiform temporary or permanent pseudopodial prolongations of the body-substance, by means of which locomotion, fixation, and ingestion are effected. There is no mouth or special ingestive area; the sarcode may be distinguishable into an outer ectoplasm and an inner endoplasm; a nucleus and nucleolus (endoplast and endoplastule) may be present; and most of these animalcules secrete a shell or test, often of great beauty and complexity. The rhizopods are minute, usually microscopic organisms, some or other forms of which abound in both salt and fresh waters. The characteristic pseudopodia are highly diverse in form, and constantly change, but occur in two principal forms, coarse lobate or digitate processes and fine slender rays, both of which may run together or interlace. The valuation and limitation of the *Rhizopoda* have varied with different authors. A normal amœboid protozoan is a characteristic example of this class. Other forms included under *Rhizopoda* are the so-called moners; the sun-animalcules, or *Heliozoa;* the *Foraminifera,* with a (usually) calcareous shell; and the *Radiolaria,* with a silicious shell. By common consent the sponges, which have been classed with *Rhizopoda,* are now excluded. See cuts under *Amœba, Foraminifera,* and *Radiolaria.* Also called *Sarcodina.*

The group, however, falls far short of the supreme excellence attributed to it by Pliny and by the art amateurs of the end of the eighteenth century. The Rhodian school is intimately connected with that of Pergamum.

(Linnæus, 1753), < Gr. *ῥοδόδενδρον*, the oleander, < *ῥόδον*, rose, + *δένδρον*, tree.] **1.** A large genus of shrubs of the family *Ericaceæ* and tribe *Rhododendreæ*. It is characterized by a broad, spreading, and oblique corolla, usually with five imbricating lobes; eight to ten stamens, the anthers opening by pores; and a five- to twenty-celled ovary with numerous ovules in many crowded rows, the seeds appendaged; there are about one hundred species, natives of the mountains of Europe, Asia, the Malay archipelago, and North America, most abundant in the Himalayas. They are commonly shrubs, less often trees, smooth, hairy, woolly, or scurfy, and often with whorled branches. They bear alternate entire leaves, most often crowded at the ends of the branches. Their handsome flowers are commonly borne in corymbs, and have conspicuous, more or less unequal, long, slender, and curving stamens, with long hairs clothing their base.

Rhododendron grande (Himalayas).

The fruit is a woody pod, splitting septicidally from the apex into valves, and filled with seeds like fine sawdust, each containing a cylindrical embryo and fleshy albumen. Most of the species, and all of those best known, produce their new growths below the flowers, which form a terminal inflorescence destitute of leaves, and developed from a large scaly bud. The leaves in the typical species, forming the section *Rhododendron* proper, are evergreen and coriaceous; but they are deciduous in the sections *Azalea* and *Tsusia*, which include the American species commonly known as *azaleas*, and produce leaves closely encircling the flowers, or, in *Tsusia*, mixed with them. The flowers, nearly or quite 2 inches across, often reach in *R. Aucklandiæ* a breadth of 6 inches. See *pinkster-flower*.

2. [*l. c.*] Any one of the many species of the above genus, belonging to the tribe *Rhododendreæ;* the rose-bay. The rhododendrons are handsome shrubs, much cultivated for their evergreen leathery leaves and profusion of beautifully formed and colored flowers. The ordinary species of American outdoor plantations is *R. Catawbiense*, the Catawba or Carolina rhododendron, hybridized with the more tender exotics *R. Ponticum* and *R. arboreum*. The Catawba species grows from 3 to 6, rarely 20, feet high, has oval or oblong leaves and broadly bell-shaped lilac-purple or (in culture) variously colored flowers. It is native in the Alleghanies from Virginia southward. It has also been largely cultivated in Europe, and there are hundreds of varieties. The great rhododendron (or laurel), *R. maximum*, abounds in the Alleghanies, and is found as far north as Maine and Canada. It is commonly taller than *R. Catawbiense*, with narrower leaves, and flowers pink or nearly white with a greenish throat. It is a fine species, but much less cultivated than the last; it affords some hybrids. The Californian rhododendron, *R. Californicum*, resembles the Catawba rhododendron, but has more showy flowers. It deserves cultivation, and has proved hardy in England. The Pontic rhododendron, *R. Ponticum*, is the most common species of European gardens, hardy only as a low shrub in the northern United States. *R. arboreum*, the tree rhododendron, is a fine Himalayan species, 25 feet high, with the leaves silvery-white beneath, and the flowers scarlet varying to white. The Lapland rhododendron, *R. Lapponicum*, is a dwarf arctic and alpine species of both hemispheres, growing prostrate in broad tufts. The Siberian or Dahurian rhododendron, *R. Dauricum*, a dwarf species, somewhat cultivated, bears its bright rose-purple flowers on naked shoots in early spring.—**Indian rhododendron.** See *Melastoma*.

Sw. *rabarber* (Turk. *rubās*), < ML. *rheubarbarum, rhubarbarum*, also *reubarbarum*, for *rheum barbarum*, < Gr. *ῥῆον βάρβαρον*, rhubarb, *ῥῆον*, rhubarb (*ῥήον*, ML. *rheum*, being appar. a deriv. or orig. an adj. form of *Pá*, the *Rha*, or Volga river, whence rhubarb was also called *rha Ponticum*, 'Pontic rha' (see *rhapontic*), and *rha barbarum*, 'barbarous (i. e. foreign) rha'): see *rha, Rheum*[2], and *barbarous*.] **I.** *n.* 1. The general name for plants of the genus *Rheum*, especially for species affording the drug rhubarb and the culinary herb of that name. The specific source of the official rhubarb was in question; but it is now practically

Medicinal Rhubarb (*Rheum officinale*).

settled that *R. officinale* is one of the probably several species which yield it. *R. palmatum, R. Rhaponticum*, and *R. leucorrhizon* also have some claims. It is produced on the high table-lands of western China and eastern Tibet, and formerly reached the western market by the way of Russia and Turkey, being named accordingly. It is now obtained from China by sea (Chinese rhubarb), but is more mixed in quality, from lack of the rigorous Russian inspection. Various species, especially *R. Rhaponticum* and *R. palmatum*, have been grown in England and elsewhere in Europe for the root, but the product is inferior, from difference either of species or of conditions. The common garden rhubarb is *R. Rhaponticum* and its varieties. It is native from the Volga to central Asia, and was introduced into England about 1573. Its leaves were early used as a pot-herb, but the now common use of its tender acidulous leafstalks as a spring substitute for fruit in making tarts, pies, etc., is only of recent date. Attempts to use it as a wine-plant have not been specially successful. Some other species have a similar acid quality. From their stature and huge leaves, various rhubarbs produce striking scenic effects, especially *R. Emodi*, the Nepal rhubarb, which grows 5 feet high and has wrinkled leaves veined with red; and still more the better-formed *R. officinale*. A finer and most remarkable species is *R. nobile*, the Sikhim rhubarb, which presents a conical tower of imbricating foliage a yard or more high, the ample shining-green root-leaves passing into large straw-colored bracts which conceal beautiful pink stipules and small green flowers. The root is very long, winding among the rocks. This plant is not easily cultivated.

2. The root of any medicinal rhubarb, or some preparation of it. Rhubarb is a much-prized remedy, remarkable as combining a cathartic with an astringent effect, the latter succeeding the former. It is also tonic and stomachic. It is administered in substance or in various preparations.

The patient that doth determine to receiue a little *Rheubarb* suffereth the bitternesse it leaueth in the throte for the profite it doth him against his feuer.
Guevara, Letters (tr. by Hellowes, 1577), p. 242.

What *rhubarb*, cyme, or what purgative drug,
Would scour these English hence?
Shak., Macbeth, v. 3. 55.

3. The leafstalks of the garden rhubarb collectively; pie-plant.—**Bog-rhubarb.** See *Petasites*.—**Compound powder of rhubarb.** See *powder*.—**False rhubarb,** *Thalictrum flavum*.—**Monk's rhubarb,** the patience-dock, *Rumex Patientia*, probably from the use of its root like rhubarb; also, a species of meadow-rue, *Thalictrum flavum*.—**Poor man's rhubarb,** *Thalictrum flavum*.

A vertical circle of the celestial sphere. So says Hutton; but if so, it is difficult to understand how Kepler (*Epitom. Astron.*, ii. 10), in order to explain def. 2, is driven to the trapezoidal figure of the points on the compass-card.

The leaves are pinnate, one- to three-foliolate, or sometimes simple; the flowers are small, in axillary or terminal panicles; the fruit is a small compressed drupe. The plant often abounds in a caustic poisonous juice and sometimes exudes a varnish. There are about 120 species, found throughout subtropical and warm climates, but infrequent in the tropics. They are especially abundant at the Cape of Good Hope, also in eastern Asia; 4 species are found in southern Europe, a few in the East Indies and the Andes, and 18 in the United States. Rhynchophora (ring-kof'ō-rä), *n. pl.* [NL., neut. pl. of *rhynchophorus*: see *rhynchophorous*.] A section of tetramerous coleopterous insects, characterized by the (usual) prolongation of the head into a snout or proboscis (whence the name); the weevils, curculios, or snout-beetles. In Latreille's classification (1807), the *Rhynchophora* were the first family of the *Coleoptera tetramera*. They have the palpi typically rigid, without distinct palpariæ, the maxillary four-jointed and the labial three-jointed; labrum typically absent; gular sutures confluent on the median line; prosternum cut off behind by the epimera, and prosternal sutures wanting; and the epipleuræ of the elytra generally wanting. The characteristic beak or rostrum varies from a mere vestige in some of these insects to three times the length of the body. The antennæ are generally elbowed or geniculate, with the basal joint or scape received into a groove or scrobe. The larvæ are legless grubs; some spin a cocoon in which to pupate. This suborder is divided into 3 series, and contains 13 families. The species are all vegetable-feeders except *Brachytarsus*, which is said to feed on bark-lice. They are very numerous, being estimated at 30,000, and many are among the most injurious insects to farm, garden, and orchard. It is characterized by its two ovules with central funiculus, by its compressed and often falcate pod, and by papilionaceous flowers with beardless style and terminal stigma. There are about 150 species, natives of warm regions, with some extratropical species in North America and South Africa. They are herbs or undershrubs, usually twining or prostrate. They bear compound resinous-dotted leaves of three leaflets, with ovate or lanceolate stipules, and sometimes with additional minute bristle-shaped stipels. The flowers are yellow, rarely purple, often with brown stripes on the keel, and are borne singly or in pairs along axillary racemes. *Dolicholus phaseoloides* of tropical America, a high-climbing vine, has the seeds black with a scarlet-yellow ring around the hilum, and from the use made of them is named *Mexican rosary-plant*. It is characterized by commonly narrow or acuminate spikelets in many and close clusters, which are terminal or apparently axillary; by an undivided or two-cleft style; and by a nut beaked at its top by the dilated and persistent base of the style. There are about 200 species, of tropical and subtropical regions, especially in America, where many extend into the United States; in the old world only two similarly extend into Europe and Asiatic Russia. They are annual or perennial, slender or robust, erect or rarely diffuse or floating, often with leafy stems. The spikelets are disposed in irregular umbels or sessile heads, which are clustered, corymbed, or panicled. Most of the species of tropical America (subgenus *Haplostylis*) have capitate spikelets, commonly one-seeded, and a long undivided slender style; those of the subgenus *Distylis* have two- to four-seeded polymorphous spikelets, and a style deeply divided into two branches. *R. corniculata*, a species of the United States, from 3 to 6 feet high, is called *horned rush*.

rhyolite (rī′ō-līt), *n.* [Irreg. < Gr. *ῥύαξ*, a stream, esp. a stream of lava from a volcano (< *ῥεῖν*, flow: see *rheum*[1]), + *λίθος*, a stone.] The name given by von Richthofen to rocks occurring in Hungary which resemble trachyte, but are distinguished from it by the presence of quartz as an essential ingredient, and also by a great variety of texture, showing more distinctly than rocks usually do that the material had flowed while in a viscous state. The name *liparite* was given later by J. Roth to rocks of similar character occurring on the Lipari Islands. Non-vitreous rocks of this kind had previously been called *trachytic porphyries*, and they have also been designated as *quartz-trachytes*. Von Richthofen proposed the name of *nevadite* (also called *granitic rhyolite* by Zirkel) for the variety in which large macroscopic ingredients, like quartz and sanidine, predominated over the ground-mass, retaining the name *liparite*, and applying it to the varieties having a porphyritic or felsitic structure, and limiting the term *rhyolite* to the lithoidal and hyaline modifications, such as obsidian, pumice-stone, and perlite; and nearly the same nomenclature was adopted by Zirkel. Rosenbusch recognizes as structural types of the rhyolitic rocks nevadite, liparite proper, and glassy liparite, remarking that these names correspond closely to Zirkel's nevadite, rhyolite, and glassy rhyolite respectively. These rocks are abundant in various countries, especially in the Cordilleran region, and are interesting from their connection and association with certain important metalliferous deposits. See cut under *axiolite*.

rhythm (riᵺhm or rithm), *n.* [Formerly also *rhithm, rithme;* < OF. *rithme, rhythme*, F. *rhythme* = Sp. It. *ritmo* = Pg. *rhythmo*, < L. *rhythmus*, ML. also *rhithmus, ritmus*, rhythm, < Gr. *ῥυθμός*, Ionic *ῥυσμός*, measured motion, time, measure, proportion, rhythm, a metrical measure or foot (cf. *ῥύσις*, a stream, *ῥύμα*, a stream, *ῥυτός*, flowing), < *ῥεῖν* (√ *ῥευ, ῥυ*), flow:

see *rheum*[1]. The word *rhythm*, variously spelled, was formerly much confused with *rime*, which thus came to be spelled *rhyme:* see *rime*[1].] **1.** Movement in time, characterized by equality of measures and by alternation of tension (stress) and relaxation. The word *rhythm* (ῥυθμός) means 'flow,' and, by development from this sense, 'uniform movement, perceptible as such, and accordingly divisible into measures, the measures marked by the recurrence of stress.' Examples of rhythm, in its stricter sense, in nature are respiration and the beating of the pulse, also the effect produced on the ear by the steady dripping of water. The three arts regulated by rhythm are music, metrics, and, according to the ancients, orchestic, or the art of rhythmical bodily movement. Rhythm in language is *meter*. The term was further extended to sculpture, etc. (compare def. 5), as when a writer speaks of "the *rhythm* of Myron's Discobolus."

We have here the three principal applications of *rhythm*, three principal domains in which *rhythm* manifests its nature and power — dancing, music, poetry.
J. Hadley, Essays, p. 81.

2. In *music:* (*a*) That characteristic of all composition which depends on the regular succession of relatively heavy and light accents, beats, or pulses; accentual structure in the abstract. Strictly speaking, the organic partition of a piece into equal measures, and also the distribution of long and short tones within measures, in addition to the formation of larger divisions, like phrases, sections, etc., are matters of *meter*, because they have to do primarily with time-values; while everything that concerns accent and accentual groups is more fitly arranged under *rhythm*. But this distinction is often ignored or denied, *meter* and *rhythm* being used either indiscriminately, or even in exactly the reverse sense to the above. (See *meter*[2].) In any case, in musical analysis, *rhythm* and *meter* are coördinate with *melody* and *harmony* in the abstract sense. (*b*) A particular accentual pattern typical of all the measures of a given piece or movement. Such patterns or rhythms are made up of accents, beats, or pulses of equal duration, but of different dynamic importance. A rhythm of two beats to the measure is often called a two-part rhythm; one of three beats, a three-part rhythm, etc. Almost all rhythms may be reduced to two principal kinds: *duple* or two-part, consisting of a heavy accent or beat and a light one (often called *march rhythm* or *common time*); and *triple* or three-part, consisting of a heavy accent or beat and two light ones (*waltz rhythm*). The accent or beat with which a rhythm begins is called the *primary accent*. Its place is marked in written music by a bar, and in conducting by a down-beat. Each part of a rhythm may be made compound by subdivision into two or three secondary parts, which form duple or triple groups within themselves. Thus, if each part of a duple rhythm is replaced by duple secondary groups, a four-part or *quadruple* rhythm is produced, or if by triple secondary groups, a six-part or *sextuple* rhythm (first variety). By a similar process of replacement, from a triple rhythm may be derived a six-part or *sextuple* rhythm (second variety) and a nine-part or *nonuple* rhythm; and from a quadruple rhythm, an eight-part or *octuple* rhythm and a twelve-part or *dodecuple* rhythm. The constituent groups of compound rhythms always retain the relative importance of the simple part from which they are derived. The above eight rhythms are all that are ordinarily used, though quintuple, septuple, decuple, and other rhythms occasionally appear, usually in isolated groups of tones. (See *quintuplet, septuplet, decimole*, etc.) In ancient music a measure did not necessarily begin with a beat, and the rhythms were the same as those indicated in metrics below (3 (*b*)). While all music is constructed on these patterns, the pattern is not always shown in the tones or chords as sounded. The time-value of one or more parts may be supplied by a silence or rest. A single tone or chord may be made to include two or more parts, especially in compound rhythms; and thus every possible combination of long and short tones occurs within each rhythm. When a weak accent is thus made to coalesce with a following heavier one, especially if the latter is a primary accent, the rhythm is syncopated. (See *syncopation.*) The regularity of a rhythm is maintained by counting or beating time — that is, marking each part by a word or motion, with a suitable difference of emphasis between the heavy and the light accents. In written music the rhythm of a piece or movement is indicated at the outset by the *rhythmical signature* (which see, under *rhythmical*). The speed of a rhythm in a given case — that is, the time-value assigned to each measure and part — is called its *tempo* (which see). Rhythm and tempo are wholly independent in the abstract, but the tempo of a given piece is approximately fixed. Although regularity and definiteness of rhythm are characteristic of all music, various influences tend to modify and obliterate its form. The metrical patterns of successive measures often differ widely from the typical rhythmic pattern and from each other. Except in very rudimentary music, purely rhythmic accents are constantly superseded by accents belonging to figures and phrases — that is, to units of higher degree than measures. Indeed, in advancing from rudimentary to highly artistic music, rhythmic patterns become less and less apparent, though furnishing everywhere a firm and continuous accentual groundwork. Rhythm is often loosely called *time*. Also called *proportion*.

3. In *metrics:* (*a*) Succession of times divisible into measures with theses and arses; metrical movement. Theoretically, all spoken language possesses rhythm, but the name is distinctively given to that which is not too complicated to be easily perceived as such. Rhythm, so limited, is indispensable in metrical composition, but is regarded as inappropriate in prose, except in elevated style and in oratory, and even in these only in the way of vague suggestion, unless in certain passages of special character.

Rhythm . . . is of course governed by law, but it is a law which transcends in subtlety the conscious art of the metricist, and is only caught by the poet in his most inspired moods.
Encyc. Brit., XIX. 262.

(*b*) A particular kind or variety of metrical movement, expressed by a succession of a particular kind or variety of feet: as, iambic *rhythm;* dactylic *rhythm.* In ancient metrics, rhythm is *isorrhythmic, direct,* or *dochmiac* (see the phrases below), or belongs to a subdivision of these. (*c*) A measure or foot. (*d*) Verse, as opposed to prose. See *rime*[1].—4. In *physics* and *physiol.*, succession of alternate and opposite or correlative states.

The longer astronomic *rhythm*, known as the earth's annual revolution, causes corresponding *rhythms* in vegetable and animal life: witness the blossoming and leafing of plants in the spring, the revival of insect activity at the same season, the periodic flights of migratory birds, the hybernating sleep of many vertebrates, and the thickened coats or the altered habits of others that do not hybernate.
J. Fiske, Cosmic Philos., I. 307.

5. In the *graphic* and *plastic arts*, a proper relation and interdependence of parts with reference to each other and to an artistic whole. — **Ascending rhythm.** See *ascending.* — **Descending or falling rhythm.** See *descending.* — **Direct rhythm,** in *anc. metrics*, rhythm in which the number of times or moræ in the thesis of the foot differs from that in the arsis by one. Direct rhythm includes diplasic, hemiolic, and epitritic rhythm, these having a pedal ratio (proportion of moræ in arsis and thesis) of 1 to 2, 2 to 3, and 3 to 4 respectively: opposed to *dochmiac rhythm.* — **Dochmiac rhythm,** in *anc. metrics*, rhythm in which the number of times in the arsis differs from that in the thesis by more than one. Dochmiac rhythm in this wider sense includes *dochmiac rhythm* in the narrower sense (that is, the rhythm of the dochmius, which has a pedal ratio of 3 to 5), and *triplasic rhythm*, characterized by a pedal ratio of 1 to 3. — **Double rhythm.** Same as *duple rhythm.* See def. 2. — **Equal rhythm, isorrhythmic rhythm,** in *anc. metrics*, rhythm in which the number of times in the thesis and arsis is equal. Also called *dactylic rhythm.* — **Imperfect rhythm.** Same as *imperfect measure.* See *imperfect.* — **Oblique rhythm.** Same as *dochmiac rhythm.* = **Syn. 2.** *Melody, Harmony*, etc. See *euphony.*

★**rhythmical** (rith′mi-kạl), *a.* [< *rhythmic* + *-al.*] **1.** Pertaining to rhythm in art, or to a succession of measures marked by regularly recurrent accents, beats, or pulses; noting any succession so marked; hence, musical, metrical, or poetic: as, the *rhythmical* movement of marching or of a dance.

Honest agitators have been moved, by passionate zeal for their several causes, to outbursts of *rhythmical* expression.

2. In *physics* and *physiol.*, pertaining to or constituting a succession of alternate and opposite or correlative states.

This *rhythmical* movement, impelling the filaments in an undeviating onward course, is greatly influenced by temperature and light.
W. B. Carpenter, Micros., vi. § 246.

3. In *med.*, periodical. — **4.** In the *graphic* and *plastic arts*, properly proportioned or balanced. — **Rhythmical signature,** in *musical notation*, a sign placed at the beginning of a piece, after the key-signature, to indicate its rhythm or time. (Also called *time-signature.*) It consists of two numerals placed one above the other on each staff, the upper numeral indicating the number of principal beats or pulses to the measure, and the lower the kind of note which in the given piece is assigned to each beat. (See *rhythm* and *note*[1], 13.) Thus, $\frac{4}{4}$ indicates quadruple rhythm, four beats to the measure, each beat marked by a quarter-note, 𝅘𝅥, or its equivalent. Difference of rhythm is unfortunately not always indicated by difference of rhythmic signature; and difference of signature often means only an unessential difference of notes rather than of rhythm. Thus, duple rhythm may be marked either by $\frac{2}{1}$, $\frac{2}{2}$, $\frac{2}{4}$, $\frac{2}{8}$, or $\frac{4}{4}$; triple rhythm, by $\frac{3}{1}$, $\frac{3}{2}$, $\frac{3}{4}$, $\frac{3}{8}$, $\frac{3}{16}$; quadruple rhythm, by $\frac{4}{1}$, $\frac{4}{2}$, $\frac{4}{4}$, $\frac{4}{8}$; sextuple rhythm (first variety), by $\frac{6}{4}$, $\frac{6}{8}$; sextuple rhythm (second variety), by $\frac{3}{2}$, $\frac{3}{4}$, $\frac{3}{8}$; octuple rhythm, by $\frac{8}{2}$, $\frac{8}{4}$, $\frac{8}{8}$; nonuple rhythm, by $\frac{9}{2}$, $\frac{9}{4}$; dodecuple rhythm, by $\frac{12}{8}$. Most of the varieties of duple and quadruple signatures are often written simply C, common; when duple rhythm is to be distinguished from quadruple, this sign is changed to ₵, or the words *alla breve* are added. The rhythmical signature is not repeated on successive braces. A decided change of rhythm is marked by a new signature; but the isolated intrusion of a foreign rhythm, especially in a short melodic group, is usually marked by a curve and an inclosed numeral, as $\overset{\frown}{4}$, $\overset{\frown}{7}$. See *triplet, quartole, quintuplet*, etc.

OHG. *hirni-reba*, MHG. *hirnrebe*, that which envelops the brain, the skull).] **1.** In *anat.* and *zoöl.*, a costa; a pleurapophysis, with or without a hemapophysis; the pleurapophysial element of a vertebra, of whatever size, shape, or mode of connection with a vertebra. In ordinary language the term *rib* is restricted to one of the series of long slender bones which are movably articulated with or entirely disconnected from the vertebræ, occur in pairs, and extend to or toward the sternum or middle ventral line of the body. In many vertebrates such ribs are characteristic of or confined to the thoracic or dorsal region, and form, together with the corresponding vertebræ and with the sternum, a kind of bony cage for the thoracic viscera—the chest or thorax. Such ribs are called *thoracic* or *dorsal*, and are often the only free ribs an animal may possess, as is usually the case in mammals. In man there are twelve pairs of such ribs. The first of these articulates with the upper part of the side of the body of the first dorsal vertebra; the second to the ninth inclusive articulate at an intervertebral space, and consequently with two vertebræ apiece; the tenth, eleventh, and twelfth articulate with the single vertebra to which they correspond. The first to the tenth ribs articulate by their heads with bodies of vertebræ as above stated, and also by their shoulders with transverse processes, which latter articulations are lacking to the eleventh and twelfth ribs. The first seven ribs reach the sternum by means of costal cartilages, and are called *true ribs;* the last five ribs do not, and are called *false ribs:* of these last the first three join one another by means of their costal cartilages, while the last two are entirely free or "floating" at their ends. Only the bony part of a rib is a pleurapophysis; the gristly part, or costal cartilage, is a hemapophysis. Parts of a bony rib commonly distinguished are the *head* or *capitulum*, the *neck* or *cervix*, the *shoulder* or *tuberculum*, and the *shaft*. Most of the ribs are not only curved as a whole, but also somewhat bent at a point called the *angle*, and, moreover, twisted on their own axis. In man there are occasionally supernumerary cervical or lumbar ribs of ordinary character, that are extended from and freely jointed to their vertebræ; and all the human cervical vertebræ have rudimentary ribs ankylosed with their respective vertebræ, represented by that part of the transverse process which bounds the vertebrarterial foramen in front. Mammals have frequently more or fewer than twelve pairs of thoracic ribs. Ribs occurring in any part of the vertebral column are named from that part: as, *cervical*, *thoracic* or *dorsal*, *dorsolumbar*, *lumbar*, or *sacral* ribs. In birds and reptiles the number of ribs is extremely variable, and their situation may extend from head to tail. Frequently they are jointed in the middle, or at the point where in a mammal the bony part joins the cartilaginous. Some of them may be free or floating at the vertebral as well as at the sternal end. Some ribs in birds bear peculiar splint-bones called *uncinate processes*. (See cut under *epipleura*.) In chelonians the ribs are fixed, and consolidated with broad plate-like dermal bones to form the carapace. The greatest number of ribs is found in some serpents, which have more than two hundred pairs. In some fishes, ribs are apparently doubled in number by forking; this is the principal reason why the bones of a shad, for example, seem so numerous. See also cuts under *carapace* and *skeleton*.

(*c*) In *arch.*: (1) In vaulting, a plain or variously molded and sculptured arch, properly, supporting a vault, or, in combination with other ribs, the filling of a groined vault. In pointed vaults the groins typically rest upon or are covered by ribs; and secondary ribs connecting the main ribs, especially in late and less pure designs, are sometimes applied, usually as a mere decoration, to the plain surfaces of the vaulting-cells. The three main vaulting-ribs are designated as (*α*) groin-ribs or ogives, (*β*) doubleaux, and (*γ*) formerets. (See plan under *arc*[1].) Ribs upon the surfaces of the cells are known as *surface-ribs*. The groin-rib or ogive is also called the *diagonal rib*, because it occupies the diagonal of the plan of a quadripartite vault. See *arch*[1] and *arc*[1].

> All these *ribs* [of Notre Dame Cathedral, Paris] are independent arches, which determine the forms of, and actually sustain, the vault shells.
> *C. H. Moore*, Gothic Architecture, p. 52.

See *midrib* and *nervation*. (2) A prominent line on the surface of some other organ, as the fruit. (*g*) In cloth or knitted work, a ridge or stripe rising from the groundwork of the material, as in corduroy. (*h*) In *bookbinding*, one of the ridges on the back of a book, which serve for covering the tapes and for ornament. (*i*) One of the narrow tracks or ways of iron in which the bed of a printing-press slides to and from impression. (*j*) In *mach.*, an angle-plate cast between two other plates, to brace and strengthen them, as between the sole and wall-plate of a bracket. (*k*) In a violin or similar instrument, one of the curved sides of the body, separating the belly from the back. (*l*) In *gun-making*, either of the longitudinally extending upper or lower projections of the metal which join the barrels of a double-barreled gun, and which in fine guns are often ornamented or of ornamental shape. The upper rib is called the *top rib;* the lower, the *bottom rib*.

It is of rare occurrence except in English medieval vaulting, and is not used in vaults of the most correct and scientific design.—**Sacral rib,** the pleurapophysis of a sacral vertebra, of whatever character. The very complex sacrarium of a bird often bears articulated or ankylosed ribs of ordinary character, called *sacral*, though these may be really lumbosacral, or dorsolumbar. No mammal has such sacral ribs; but the whole "lateral mass," so called, of a mammalian sacrum, as in man, which ossifies from several independent centers, is regarded by some anatomists as pleurapophysial, and therefore as representing a consolidation of sacral ribs.—**Surface-rib,** in *arch.*, a rib without constructive office, applied to the surface of vaulting merely for ornament; a lierne, tierceron, etc. Such ribs, as a rule, were not used until after the best time of medieval vaulting.—**To give a rib of roast**† to rib-roast; thrash soundly. Francisco *Ricci,* an Italian botanist.] A genus of cryptogamous plants of the class *Hepaticæ,* typical of the family *Ricciaceæ.* They are delicate little terrestrial or pseudo-aquatic, chiefly annual, plants with thallose vegetation. The thallus is at first radiately divided from the center, which often soon decays; the divisions are bifid or ditrichotomous; the fruit is immersed in the thallus, sessile; and the spores are alveolate or muriculate, flattish, and angular. There are 107 species, of most parts of the world.

(Endlicher, 1836), < *Riccia* + *-aceæ.*] A family of thallose cryptogamous plants of the class *Hepaticæ,* typified by the genus *Riccia.* They are regarded as having the simplest structure in the class. The thallus is usually flat, branching dichotomously, and floating on water or rooting in soil. The fruit is short-pedicelled or sessile on the thallus or immersed in it; the capsule is free or connate with the calyptra, globose, rupturing irregularly; the spores are usually angular; and elaters are wanting. Besides *Riccia* the family contains the genera *Ricciocarpus* and *Tesselina,* monotypic genera of wide distribution.

Skt. *vrīhi,* rice.] 1. The grain of the rice-plant. It forms a larger part of human food than the product of any other one plant, being often an almost exclusive diet in India, China, and the Malayan islands, and abundantly used elsewhere. Over 75 per cent. of its substance consists of starchy matter, but it is deficient in albuminoids, the flesh-forming material, and is thus best adapted for use in warm climates. It is commonly prepared by boiling; in warm countries it is much employed in curries. Rice-flour, rice-glue, rice-starch, rice-sugar, and rice-water are made from it; the *sake* of the Japanese is brewed from rice, and one kind of true arrack is distilled from it.

2. The rice-plant, *Oryza sativa.* It is a member of the grass family (see *Oryza*), native in India, also in northern Australia; extensively cultivated in India, China, Malaysia, Brazil, the southern United States, and somewhat in Italy and Spain. It has numerous natural and cultivated varieties, and ranges in height from 1 to 6 feet. It requires for ripening a temperature of from sixty to eighty degrees, and in general can be grown only on irrigable land (but see *mountain-rice*). Rice is one of the most prolific of all crops. It was introduced into South Carolina about 1700—it is said by chance. The finest quality is produced in the United States, Louisiana and Texas leading in amount; but the production has considerably declined since the civil war.—**Canada rice.** Same as *Indian rice.*—**False rice,** a grass of the genus *Homalocenchrus.*—**Hungary rice,** a corruption of *hungry rice.*—**Hungry rice.** Same as *fundi.*—**Indian rice.** (*a*) A reed-like grass, *Zizania aquatica,* common in shallow water in eastern North America, and especially abundant northwestward. The seeds, which are slender and half an inch long, are farinaceous, much eaten by birds, and largely gathered by the Indians in canoes; but they fall so easily as to render the plant unfit for cropping. The straw has been recommended as a paper-stock. Its height and large monœcious panicle render it a striking plant. A more southerly species, *Zizaniopsis miliacea,* is included under the name. Also called *Canada* or *wild rice,* and *Indian oats* or *water-oats.* (*b*) Rice produced in India.—**Millet-rice,** the East Indian *Echinochloa colona.*—**Petty-rice.** See *Quinoa.*—**Rice cut-grass.** See *cut-grass.*—**Rice-grain decoration,** in *ceram.,* a kind of decoration used in porcelain, especially Chinese, and in fine earthenware, as sometimes in Persian work. Occasionally the openings are of different shapes, as small stars, crosses, etc.—**Rough rice,** the common name for the East Indian paddy or unhusked rice.—**Water-rice, wild rice.** Same as *Indian rice.*

A name commonly but erroneously applied to a delicate white film prepared in China from the pith of a shrub, *Tetrapanax papyrifer*. The pith freed from the stem is an inch or an inch and a half in diameter, and is cut into lengths of about three inches. These by the use of a sharp blade are pared into thin rolls which are flattened and dried under pressure, forming sheets a few inches square. The Chinese draw and paint upon these, and they are much used in the manufacture of artificial flowers, some pith being imported in the stem for the same purpose. In the Malay archipelago the pith of *Lobelia Kœnigii* furnishes the rice-paper. See *Fatsia*.—**Rice-paper tree,** a small tree, *Tetrapanax papyrifer*, native in the swamps of Formosa, and cultivated in China, whose pith forms the material of so-called rice-paper. It grows 20 feet high or less, has leaves a foot across, palmately five- to seven-lobed, and clusters of small greenish flowers on long peduncles. From its ample leaves and stately habit, it is a favorite in subtropical planting. The Malayan rice-paper plant, *Lobelia Kœnigii*, is a sea-shore shrub found from India to Australia and Polynesia. Its young stems are stout and succulent, and yield a pith used like that of *Tetrapanax*, though smaller. It is the taccada of India and Ceylon.

Richardia (ri-chär′di-ą), *n.* [NL. (Kunth, 1818), named from the French botanists L. C. M. *Richard* (1754–1821) and his son Achille *Richard* (1794–1859).] 1. A name given by Kunth in 1818 to *Aroides*, a genus of monocotyledonous plants of the family *Araceæ*. It comprises perennial stemless herbs, with monœcious flowers without perianth, the two sexes borne close together on the same spadix. The male flowers bear two or three stamens, the female three staminodia. The ovoid ovary ripens into a berry of from two to five cells, each containing one or two anatropous albuminous seeds. The leaves are sagittate, and the spadix is surrounded with an open white or yellow spathe, the persistent base of which adheres to the fruit. *Aroides Æthiopicum* is the common calla (the *Calla Æthiopica* of Linnæus), often called *calla-lily* on account of its pure white spathe. Also called *African* or *Ethiopian lily*, and *lily of the Nile*, though it is native only in South Africa. *A. albo-maculatum*, having the leaves variegated with translucent white spots, is also cultivated. There are in all 6 species.

riffle[1] (rif'l), *n.* [< Dan. *rifle*, a groove, channel: see *rifle*[2], *n.*] 1. In *mining*, the lining of the bottom of a sluice, made of blocks or slats of wood, or stones, arranged in such a manner that chinks are left open between them. In these chinks more or less quicksilver is usually placed, and it is by the aid of this arrangement that the particles of gold, as they are carried downward by the current of water, are arrested and held fast. The whole arrangement at the bottom of the sluices is usually called *the riffles*. In the smaller gold-saving machines, formerly much used, as the cradle, the slats of wood nailed across the bottom for the purpose of detaining the gold are called *riffle-bars* or simply *riffles*.

2. A piece of plank placed transversely in, and fastened to the bottom of, a fish-ladder. The riffles do not extend from side to side, but only about two thirds across. If the first riffle is fastened on the right side of the box at right angles to its side, it will extend about 30 inches across the box; the next, about 4 feet above, will be fastened on the left side of the box; the next, about 4 feet above, on the right side; and so on alternately until the top is reached. The water passing into the top is caught by the riffles and turned right and left by them until it reaches the stream below. Riffles furnish the fish a resting-place in scaling a dam.

3. In *seal-engraving*, a very small iron disk at the end of a tool, used to develop a high polish.

riffle[2] (rif'l), *n.* [Appar. a dim. of *riff*[2], prob. associated with *ripple*[2].] A ripple, as upon the surface of water; hence, a rapid; a place in a stream where a swift current, striking upon rocks, produces a boiling motion in the water. [Local, U. S.]

Cf. OIt. *raffola, ruffola*, "by *riffraffe*, by hooke or crooke, by pinching or scraping" (Florio).] 1. Scraps; refuse; rubbish; trash.

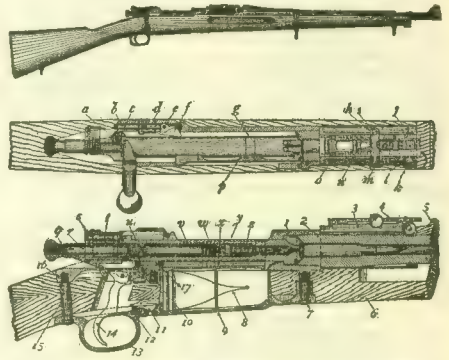
rifle[2] (rī'fl), *v.*; pret. and pp. *rifled*, ppr. *rifling*. [In sense 1, < F. *rifler*, scratch, scrape: cf. Dan. *rifle*, rifle, groove (*riflede söiler*, fluted columns; > *rifle*, a groove, flute), = Sw. *reffla*, groove, chamfer (*reffelbössa*, a rifled gun). Cf. G. *riefe*, a furrow (< LG.), *riefen*, rifle; and see *riffle*[1].] I. *trans.* 1. In *gun-making*, to cut spiral grooves in (the bore of a gun-barrel). Grooves are now in universal use for military arms as well as for all calibers of cannon. Small-arms are rifled by a cutting-tool attached to a rod and drawn through the barrel, while at the same time a revolution on the longitudinal axis is imparted to the tool. Rifled cannon are rifled by pushing through their bores a cutting-tool mounted on an arbor that exactly fits the bore.

2. [< *rifle*[3], *n.*] To whet, as a scythe, with a rifle. [Local, Eng. and New Eng.]



II. *intrans.* To groove firearms spirally along the interior of the bore.

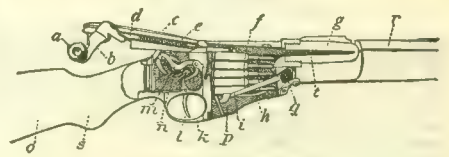
rifle[2] (rī'fl), *n.* [< *rifle*[2], *v.* Cf. Sw. *reffelbössa*, a rifled gun. Cf. Flem. *rijffel*†, LG. *riffel*, Dan. *rifle*, Sw. *reffla*, groove, flute.] 1. A spiral groove cut in the interior of a gun-barrel; hence, a firearm or a piece of ordnance having such grooves. Spirally grooved gun-barrels are of German origin; some authorities think they were invented by Gaspard Kollner of Vienna, in 1498; others regard Augustus Kotter of Nuremberg as the originator, the invention, according to these writers, dating between 1500 and 1520. Straight grooves were used in the fifteenth century, but their purpose was simply to form recesses for the reception of dirt and to aid in cleaning the gun. Spiral grooving has a distinct object beyond this, namely, to impart to the projectile a rotation whereby its flight is rendered more nearly accurate—the principle being that, when the center of gravity in the bullet does not exactly coincide with its longitudinal axis, as is nearly always the case, any tendency to deviate from the vertical plane including that axis will, by the constant revolution of the bullet, be exerted in all directions at right angles with its geometrical axis. A variety of shapes in the cross-sections of the grooves have been and are still used. The number of grooves is also different for different rifles, as is the pitch of the spiral—that is, the distance, measured on the axis of the bore, included by a single turn of the spiral. The variation in small-arms in this particular is wide—from one turn in 10 inches to one turn in 7 feet. In ordnance the pitch is much greater. Breech-loading guns began to appear in the first half of the sixteenth century, and were probably either of French or German origin. Such guns were made in Italy in the latter half of the sixteenth century. During the war of independence in America, a breech-loading rifle invented by Major Patrick Fergusson, and known as the Fergusson rifle, was used; it was the first breech-loading carbine used in the British regular army. A great many breech-loading rifles have since appeared. Muzzle-loading rifles have been superseded as military arms by these guns, and to a large extent the latter have supplanted muzzle-loaders for sporting arms. Many breech-loaders once of importance in American and European warfare have in their turn been superseded by improved arms. Among them is the once justly celebrated Prussian needle-gun. These improvements have culminated in the U. S. magazine and other repeating arms, which admit of refined accuracy of aim with great rapidity of firing. The tendency has for many years been toward smaller bores. A decided step in this direction took place in 1885–90, in the general reduction of caliber from about .45-inch to about .30-inch, and culminated in 1894 in the adoption of some rifles of about .24-inch caliber. Later, the very small bore rifles were abandoned and the universal caliber is now about .30-inch. All these arms are made to give high velocities and this has necessitated a change in the character of the bullet from soft lead to hardened lead and finally to the present steel-jacketed bullet. The range and danger-

space of these rifles are much greater than of those formerly in use. Exclusive of repeating rifles or magazine-guns, the principal differences between modern rifles are in their breech-actions and their firing-mechanism. Some of the more important of these arms are described below. See also articles in the supplement.



2. A soldier armed with a rifle: so named at a time when the rifle was not the usual weapon of the infantry: as, the Royal Irish *Rifles*—that is, the 83d and 86th regiments of British infantry.—**Albini-Braendlin rifle**, prior to 1889 the firearm of the Belgian government.—**Berdan rifle**, a combination of the Albini-Braendlin and the Chassepot rifles (which see). It is named after its inventor, an American, General Berdan. It has a hinged breech-block, which, when turned forward over the barrel, extracts the spent cartridge. A new cartridge having been inserted, the block is closed, and fastened by a bolt analogous to the lock of the Chassepot rifle. The lock has a spiral mainspring which drives the locking-bolt against a striker working in the center of the breech-block, instead of at the side as in the Albini-Braendlin gun. This rifle was used in the American civil war, and was at one time the adopted arm of the Russian government, which manufactured an improved pattern of the gun at its arsenal at Tula. The arm is hence called in Europe the Berdan-Russian rifle.—**Berthier rifle**, a rifle (carbine) invented by M. Berthier, adopted for the French cavalry in 1890. It is a bolt-gun with a box-magazine, capable of containing three cartridges, which is filled by means of clips or chargers, which are then thrown away. The caliber of the carbine is 8 millimeters (.315 inch), the weight of the bullet 208 grains, and the muzzle velocity about 2,000 feet per second. —**Breech-loading rifle**, in distinction from *muzzle-loading rifle*, a rifle that is charged at the breech instead of at the muzzle.—**Chassepot rifle**, a French modification of the Prussian needle-gun (which see). The barrel has four deep grooves with a left-handed instead of a right-handed spiral, this direction being chosen to counteract the disturbing effect of the pull-off on the aim. The self-consuming cartridge was originally used, but, this causing the gun to foul quickly, the arm has been adapted to the use of metallic cartridges.—**Double rifle**, a double-barreled rifle. Such rifles have hitherto been used only as sporting guns.—**Enfield rifle**, a muzzle-loading gun formerly manufactured by the English government at Enfield. The gun in its original form continued to be used by native regiments in India, but was converted into a breech-loader, and called the "Snider Enfield" or "Snider rifle." It was elsewhere superseded.—**Express-rifle.** See *express*, *n.*, 5.—**Francotte-Martini rifle**, a gun having the Martini breech-action with an important modification by M. Francotte of Liège, whereby the lock-mechanism may be, for cleaning, all removed at once from below, by taking out a single pin from the trigger-plate and guard to which the lock-work is wholly attached, and by which it is supported in the breech-action body. —**Henry repeating rifle**, a gun in which a magazine for cartridges extends under the entire length of the barrel, and holds fifteen cartridges. It can be fired thirty times per minute, including the time necessary to supply the magazine. The Winchester rifle superseded this arm, which was one of the weapons used in the United States army during the American civil war.—**High-powered, low-powered rifles.** See *powered*.—**Krag-Jorgensen rifle**, the military arm used by Denmark and Norway and, in an improved form, by the United States up to 1904. See *United States rifle*.—**Lebel rifle**, the rifle adopted for the French infantry in 1886. It is a bolt-gun with a tubular magazine holding eight cartridges under the barrel. The caliber is 8 millimeters (.315 inch), the weight of the bullet 208 grains, and the initial velocity 2,073 feet per second. The ammunition supply for each man is 120 rounds.—**Lee-Metford rifle**, the magazine-gun adopted in 1889 for use in the English army. It is also known as the Lee-Speed, and is nearly identical with the Remington-Lee. It is a bolt-gun, and has a detachable box-magazine, which, however, is not entirely separated from the gun, but when withdrawn from its seat is secured to the guard-swivel by a short chain. The magazine has a cut-off, so that the gun may be used as a single-loader and the magazine held in reserve. The magazine of the Mark I gun holds eight cartridges, and that of the Mark II ten cartridges. The caliber of the Lee-Metford is .303 inch, the weight of the bullet 216 grains, and the muzzle velocity 2,100 feet per second.—**Lee straight-pull rifle.** See *United States navy rifle*.—**Mannlicher rifle**, a repeating rifle adopted by Austria, Peru, and Chile in 1888, and by Holland and Rumania in 1893. It is a bolt-gun having a fixed magazine-box into which is introduced from above, through the receiver, a metal packet holding five cartridges. After the cartridges have been fed into the chamber, the packet falls to the ground through a cut in the bottom of the box. There is no cut-off, and the gun can be used only as a single-loader when the magazine is empty. The caliber of the model of 1896 is 6 millimeters (.234 inch), and the gun gives an initial velocity of 2,526 feet per second.—**Martini-Henry rifle**, a rifle adopted by the English government, rifled on the Henry principle of varying the depth of groove, and having the Martini breech-action, in which the breech-block is hinged, and opened by pushing downward and forward a lever pivoted just back of the trigger-guard, which movement also automatically extracts the cartridge-case. The gun has been slightly improved since its adoption. It is now used with a coiled brass bottle-necked cartridge carrying a large charge of powder. It shoots accurately at 800 yards, but has a range of 1,500 yards. It was superseded by the Lee-Metford in 1889.—**Match-rifle**, a fine, well-made arm used for match-shooting.—**Mauser rifle**, a military rifle adopted first by Belgium and later by Spain, Germany, and the Argentine Republic. It is a bolt-gun, and the magazine-box, having a capacity of five cartridges, is underneath the receiver and in front of the trigger-guard. The magazine is of the fixed type, but so arranged that it can readily be removed for cleaning. It can be charged through the receiver with single cartridges, or the five can be stripped at once from a metal clip. The clip is pushed out to the right as the bolt is closed, and does not form any part of the magazine mechanism. The gun has no cut-off, but a single-loading fire can be maintained, retaining four cartridges in the magazine, by replacing the top cartridge after each discharge. The caliber of the Belgian Mauser is .301 inch, the weight of the bullet 219 grains, and the initial velocity 1,968 feet per second.—**Minié rifle**, a rifle using the Minié ball.—**Muzzle-loading rifle**, a rifle which is charged or loaded at the muzzle, as distinguished from a breech-loading rifle.—**Peabody-Martini rifle**, a breech-loading military firearm, made at Providence, Rhode Island. It is a modification of the English Martini-Henry rifle, and was used by the armies of Turkey and Rumania.—**Peabody rifle**, the first breech-loader which used a dropping breech-block pivoted at the rear end above the axis of the bore. The operating lever is also the trigger-guard, and is connected with the block in such manner that pressing it forward pulls downward the front end of the block, thus rendering it impossible to jam the block by any expansion of the cartridge at the base, as sometimes has occurred in rifles wherein the whole block slides downward below the bore. This breech-action appears to have been the forerunner of the breech-actions of the Martini, Westley-Richards, Swinburne, Stahl, Field, and other arms that have appeared since 1862 (the year in which the Peabody rifle was first submitted to military tests at the United States arsenal in Watertown).—**Remington rifle**, an arm once extensively used in the armies of the United States, France, Denmark, Austria, Italy, China, Egypt, and many South American governments. The bore has been made either to take a bottle-necked cartridge, as do the Martini-Henry and some express-rifles, or a Berdan cartridge. The breech-action of the earlier patterns has been criticized as lacking solidity, but no other military rifle has ever proved more generally satisfactory in use. The construction is remarkably simple. The breech-action of earlier patterns consisted mainly of two pieces—a combined breech-piece and extractor, and a hammer breech-bolt. Each of these parts works upon a strong center-pin with a breech-bolt to back up the breech-piece, and a spring holds the latter till the hammer falls. The action has, however, been much improved in later models, and the earlier defects removed. The breech-block is actuated by a side-lever, and it is locked independently of the hammer. It is provided with a powerful and durable extractor, and the lock-mechanism is both simple and strong. The principle of the Remington-Lee rifle was adopted by the government of Great Britain in 1889 in the Lee-Metford.—**Repeating rifle**, a rifle which can be repeatedly fired without stopping to load.—**Rook and rabbit rifle**, a small breech-loading sporting rifle, used only for short ranges.—**Saloon rifle**, a small, smooth-bore, breech-loading gun, incongruously named, having a strong heavy barrel, and used for ranges of from 50 to 100 feet. The cartridge is a small copper case charged with a fulminate. Such guns are principally used in shooting-galleries or rifle-saloons. The best of these guns shoot with remarkable accuracy, and hence are called by the French "carabines de précision."—**Schneider repeating rifle**, a gun having a reciprocating block like the Sharps rifle, the block moving down vertically, instead of being pivoted on hinges and turning downward as in actions of rifles of the Peabody type. It has a tubular magazine with a spring-coil feed extending under the barrel. The breech-block is depressed by moving an under lever downward and forward, and at the lowest position of the lever a cartridge is delivered rearward upon the top of the block. The lever is then moved back, thus lifting the cartridge into line with the bore, on arriving at which it is automatically thrust into the breech by a swinging cam on the left side of the breech-block. This cam also acts as the extractor when the breech is again opened. A link connecting the lever and hammer cocks the gun.—**Schulhof repeating rifle**, a gun having a striker of the bolt form, resembling that of the Chassepot and other guns of that class, a spacious and handy magazine in the stock-butt, a peculiar and efficient cartridge-carrier, and a trigger unlike that in any other rifle. The trigger is on the top of the grip of the stock, and is pressed instead of pulled in firing. Turning over the breech-block and drawing it rearward cocks the gun, and at the same time brings a cartridge into position for insertion; closing the block thrusts in the cartridge, leaving the gun cocked; pressing the trigger fires it. This is one of the most simple and rapid of repeating arms. Twenty-five well-aimed shots can be fired with it by an expert in thirty seconds.—**Sharps rifle**, a rifle having a nearly vertical breech-block sliding in a mortise behind the fixed chamber in the barrel, and operated from below by a lever, which forms the trigger-guard. This gun was used in the American civil war, and was also used to a very limited extent in the British cavalry. It has now only historical importance.—**Snider rifle**, an Enfield rifle converted into a breech-loader. (Compare *Enfield rifle*.) In the change, two inches in length of the breech was cut away at the top, and a slightly tapered chamber made for the reception of the cartridge. A breech-block hinged on the right-hand side was used to close the opening thus made. This block closes down behind the cartridge and receives the recoil. The block is opened, and the cartridge pushed in by the thumb. A striker passes through the breech-block, and transmits the blow of the hammer to the fulminate. The general principle of the breech-action is among the earliest known in the history of breech-loading arms.—**Soper rifle**, an arm having a side-hinged swinging block like the Wendl (Austrian) breech-loading rifle. The block is, however, operated by a lever situated on the side of the stock in a position where it can be depressed by the thumb of the right hand, while the gun is at the shoulder, without moving the hand from the grip of the stock. The movement of the lever simultaneously opens the breech-block, extracts the cartridge, carries back the striker in the breech-block, and places the hammer at full cock. The cartridge is then inserted with the left hand, and on releasing the lever from pressure the breech-block closes. The gun is then ready to fire. The possible rapidity of firing with this gun is probably greater than that of any other breech-loader not of the repeating class.—**Springfield rifle**, a single breech-loader adopted and manufactured (at Springfield in Massachusetts) by the United States government prior to 1892. The breech-fermeture consists of a rotating breech-block and a locking-cam. It is fired by means of a side-lock and firing-pin.—**United States rifle**, model of 1903, chambered for model of 1906 ammunition, the rifle of the United States army. It is a compromise between the old rifle and the carbine. The total length is 43.212 inches and the barrel, which is incased in wood to within a short distance of the muzzle, is 24.006 inches long.

The operating parts consist principally of the bolt and magazine mechanisms. The bolt mechanism is similar to that of the model 1892 rifle but strengthened against the bore pressure by additional lugs. The magazine mechanism consists of the floor-plate, magazine-spring, follower, and cut-off. The magazine is of the fixed type underneath the receiver and in front of the trigger-guard; it is filled from a clip holding five cartridges; when empty the follower holds the bolt open and calls the attention of the soldier to the necessity of refilling; it may be cut off if desired and the rifle used as a single-loader, in which case any cartridges in the magazine are held in reserve. The caliber is .30 of an inch, the weight of the bullet 150 grains, the weight of the powder charge 50 grains, and the muzzle velocity 2,700 feet per second. Twenty-five aimed shots may be fired in one minute. The maximum range is about 5,465 yards, for which the time of flight is 31.359 seconds. The penetration in white pine at 500 yards is about 24 inches and a low steel plate .3843 of an inch thick is penetrated at 100 yards. The point-blank danger space is about 650 yards. The rifle is furnished with a long knife-bayonet and the total weight is about 10 pounds.—**United States navy rifle**, the rifle adopted for the United States navy in 1895, but later abandoned: also known as the Lee straight-pull rifle. See the

supplement.—**Vetterlin repeating rifle**, a Swiss arm, of which its inventor, Vetterlin, has produced several patterns. Its firing-mechanism acts on the same principle as that of the Chassepot, but it has a magazine placed longitudinally under the barrel. The cartridges are respectively delivered rearward into a carriage which is moved upward into proper relation with the barrel by a bell-crank connected with the sliding-block when the latter is pulled backward, and descends again for another cartridge when the breech-block is closed. The extractor is similar to that of the Winchester rifle (see cut below). A coiled mainspring drives the needle against the base of the cartridge.—**Winchester rifle**, a rifle the main features of which were invented by Horace Smith and D. B.

a, rifled barrel; *b*, stock; *c*, *c*, receiver, which contains all the internal lock-mechanism, and is attached to the barrel by a screw-thread as shown at *e*, and to the wooden stock *b* by the tangs *d* and *d'* through which screws pass, one passing entirely through and binding both tangs tightly against the stock; *f*, the magazine, containing cartridges *g*, which are pressed toward the rear by the long coiled spring *h* into a recess in a vertically moving carrier-block *i* in the receiver *c*; *j*, the carrier-lever, pivoted at *k* to the finger-lever *m*, *m*, *m*, *m*, which is also pivoted to the receiver by the same pivot *k*; *l* and *l'* are abutments respectively on the carrier-lever and finger-lever, whose action is explained below; *n*, the carrier-lever spring, which holds it downward when not lifted by the finger-lever; *o*, one of the two links or toggles pivoted to the receiver at *o'*, to the breech-block *p* at *o''*, and toggle-jointed at *o'''*; *q*, a pin attached to the finger-lever and working in the slot *r* of the link *o*; *p'*, the firing-pin, which slides in the breech-

pin and whose point is driven against the cartridge by the hammer *s* at the instant of firing; *t*, the mainspring, connected by a link with the hammer below the hammer-pivot *u*; *v*, the sear with sear-spring and safety-catch mechanism (not lettered) situated behind it; *w*, the trigger; *x*, extractor and extractor-mechanism, the extractor engaging the rim of the cartridge in the barrel and pulling the spent cartridge-shell out when the breech-block is moved rearward. Turning the finger-lever *m*, *m*, *m*, *m* downward toward the front forces the breech-block, breech-pin, and hammer rearward, cocking the hammer and extracting the spent cartridge-shell. At the same time the ledge or abutment *l'* on the finger-lever presses against the ledge *l* on the carrier-lever, forcing up the carrier *i*, with its contained cartridge. When moved back to its original position the finger-lever permits the carrier to return to its original position and receive another cartridge from the magazine *f*, and also forces the breech-block *p* forward, pressing the cartridge into the breech of the barrel. The hammer remains cocked until the trigger is pulled. The loading of the gun and cocking for firing are thus effected by the single motion forward and rearward of the finger-lever *m*. The opening of a side plate (not shown) permits the charging of the magazine by successive insertions of cartridges.

Wesson about 1854, and which has been improved by B. T. Henry and others. Since 1866 it has been manufactured in substantially its present form by the Winchester Repeating Arms Co., whence its name.

Such balls are not now made spherical, as formerly, but generally cylindrical, with a conoidal head; if of lead the base is hollowed out or the sides cannelured to cause the bullet to expand into the grooves of the bore of the weapon. See *rifle*[2], *v. t.*, and cut under *bullet*.

rifle-bird (rī′fl-bėrd), *n.* An Australian bird of paradise, *Ptilorhis paradisea*, belonging to the slender-billed section (*Epimachinæ*) of the family *Paradiseidæ:* said to have been so named by the early colonists from suggesting by its colors the uniform of the Rifle Brigade. This bird is 11 or 12 inches long, the wing 6, the tail 4½, the bill 2; the male is black, splendidly iridescent with fiery,

rifling[1] (rī′fling), *n.* [Verbal n. of *rifle*[1], *v.*] 1. The act of plundering or pillaging.—2. *pl.* The waste from sorting bristles.

rifling[2] (rī′fling), *n.* [Verbal n. of *rifle*[2], *v.*] 1. The operation of cutting spiral grooves in the bore of a gun.—2. A system or method of spiral grooving in the bore of a rifle. Whatever may be the form of cross-section in the grooves, the modern practice is to make them, for small-arms, extremely shallow; and, though the rectangular form with sharp angles is still retained, the angles are commonly rounded, this being an easier form to keep clean. The system of rifling used in most military rifles has four grooves; and the grooves make one turn in about ten inches. The grooves are broad, rectangular, and very shallow, with rounded angles, the lands being much narrower than the grooves. With this system steel-jacketed bullets are necessary. The system most in vogue in America for match-rifles is that of a uniform spiral, one turn in 18 inches, with very shallow grooves. With shallow grooves, hardened bullets are required; and the method of shallow grooving, with hardened bullets, is now taking the place of deep grooves and soft bullets, which were characteristic of Whitworth's and Henry's system of rifling. In express-rifles the rifling is very shallow with a slow spiral (one turn in 4 feet to one turn in 6 feet); and six is considered the best number of grooves. The so-called "Metford system" of rifling, used in England for fine match-rifles, employs five extremely shallow grooves, each including about 32° of the circumference of the bore, the twist of the spiral increasing toward the muzzle, generally finishing with one turn in 17 inches; but it is part of this system to vary the spiral in different guns according to the character of the powder to be used. In large-bore rifles with shallow circular-arc-bottomed grooves, the grooves are often ten in number, with one turn in 7 feet. In the system called *non-fouling*, used for match-rifles, the barrel is rifled in its front half only. Some very fine shooting has been done by guns thus rifled. The Whitworth system of rifling is that of a hexagonal bore with spiral faces. It has been abandoned for ordnance. The projectiles for such rifles are also hexagonal with twisted sides. The Haddan system of rifling for ordnance consists of three spiral grooves of deep elliptical cross-section, into which fit three wings on the front of the shot or shell. Other shapes of grooves were once used for ordnance.—**Ratchet-rifling**, a kind of grooving in gun-barrels in which the grooves have a cross-section closely approximating a right-angled triangle with the hypotenuse at the bottom of the groove, like the spaces between the teeth of a ratchet. It is now used only for inferior guns.

rifling-machine (rī′fling-ma-shēn″), *n.* A machine serving to cut spiral grooves or rifles in the surface of the bore of a small-arm or cannon. For small-arms, the cutter-head is armed with two or more cutters, and the grooves are cut in the pulling stroke of the rifling rod to prevent bending, no work being done on the return stroke. After every stroke the cutter-head or barrel is revolved a certain angular distance (depending on the number of grooves to be cut) by the automatic rotation of the rifling bar, so that the several grooves are successively occupied by each cutter. For cannon, the cutter-head fits the bore exactly, and the cutter projects above its cylindrical surface to a height equal to the depth of the chip to be taken out at each stroke, cutting but one groove at a time. The twist is obtained automatically by means of a rack and pinion. The pinion-wheel is made fast to the cutter-bar, and gears into a rack carrying two or three friction-wheels at one end. These friction-wheels roll upon an inclined guide, curved or straight according as the twist is to be increasing or uniform.

rifling-tool (rī′fling-tōl), *n.* An instrument for rifling firearms.

Hence the two words may often be properly opposed. We may say that a poor man has no Right to relief, but it is *right* he should have it. 4. In *law,* that which any one is entitled to have, or to do, or to require from others, within the limits prescribed by law (*Kent*); any legal consequence which any person, natural or artificial, is entitled to insist attaches to a given state of facts; the power recognized by law in a person by virtue of which another or others are bound to do or forbear toward or in regard of him or his interests; a legally protectable interest. In this sense things possess no rights; but every person has some rights irrespective of power to act or to compel the acts of others, as, for instance, an idiot, etc.; and even the obligations of persons in being, in view of the possibility of the future existence of one not yet in being, are the subject of what are termed *contingent rights.* In this general meaning of *right* are included—(*a*) the just claim of one to whom another owes a duty to have that duty performed; (*b*) the just freedom of a person to do any act not forbidden or to omit any act not commanded; (*c*) the title or interest which one person has in a thing exclusive of other persons; and (*d*) a power of a person to appoint the disposition of a thing in which he has no interest or title. *Right* has also been defined as a legally protected interest. A distinction is made between *personal* and *real rights.* The former term is often used in English law for a right relating to personal, the latter for a right relating to real property. But in the language of writers on general jurisprudence and on civil law, a personal right is a right exclusively against persons specifically determined, and a real right is a right availing against all persons generally. By some writers a distinction is taken between *primary rights* and *sanctioning rights,* by the latter being meant the rights of action which the law gives to protect the primary rights, such as ownership, or contracts.

E. also *rightuous*, the termination *-u-ous*, later *-e-ous*, being a corruption of the second element of the orig. compound (appar. simulating *ingenuous, bounteous, plenteous*, etc.), the proper form existing in early mod. E. as *rightwise*, < ME. *rightwise, rightwis, richtwise, rigtwis, rygtwys, rihtwis*, < AS. *rihtwīs* (cf. OHG. *rehtwīsic*, Icel. *rēttvīss*), righteous, just; heretofore explained as lit. 'wise as to what is right,' < *riht*, n., right, + *wīs*, a., wise; but such a construction of ideas would hardly be expressed by a mere compound, and the explanation fails when applied to the opposite adj. **wrangwīs*, ME. *wrangwis, wrongwise, wrongwis*, mod. E. *wrongous*, which cannot well mean 'wise as to what is wrong' (though this adj. may have been formed merely on the external model of *rihtwīs*). The formation is, no doubt, as the cognate OHG. form *rehtwīsic*, which has an additional adj. suffix, also indicates, < AS. *riht*, a., right, just, + *wise*, n., way, manner, wise (reduced to *-wis* in comp., as also in Icel. *ōdhurvīs* = E. *otherwise;* the Icel. *rēttvīss*, prop. **rēttvīs*, simulates *vīss* = E. *wise*); the compound meaning lit. =**Syn. 1.** *Righteous, Rightful, Upright, Just;* honest, equitable, fair; godly, holy, saintly. The first three of the italicized words go back directly to the first principles of right, while *just*, though expressing quite as much conformity to right, suggests more of the intricate questions arising out of the relations of men. *Upright* gets force from the idea of physical perpendicularity, a standing up straight by the standard of right; *righteous* carries up the idea of right to the standards, motives, and sanctions of religion; *rightful* applies not to conduct, but to claims by right: as, he is the *rightful* owner of the land; *just* suggests by derivation a written law, but presumes that the law is a right one, or that there is above it, and if necessary overruling it, a law of God. This last is the uniform Biblical usage. *Just* generally implies the exercise of some power or authority. See *justice* and *honesty*.

Active righteousness, passive righteousness. Luther ("Commentary on the Epistle to the Galatians," Introd.) and other Protestant theologians following him distinguish

between *active* and *passive righteousness*, the former consisting in what is right because it is right, the latter in accepting for Christ's sake by faith the free gift of righteousness as defined in the second definition above.—**Original righteousness**, in *scholastic theol.*, the condition of man as made in the image of God before the fall.—**Proselytes of righteousness.** See *proselyte*.—**The righteousness of God** (Rom. i. 17), a phrase defined antagonistically by Biblical interpreters as "Righteousness which proceeds from God, the relation of being right into which man is put by God—that is, by an act of God declaring him righteous" (*Meyer*), and as "The attribute of God, embodied in Christ, manifested in the world, revealed in the Gospel, communicated to the individual soul, the righteousness not of the law, but of faith" (*Jowett*). The former is the general Protestant view; the latter comes near the view of the Roman Catholic Church, Greek Church, etc. The one regards *righteousness* as indicating a relation, the other as descriptive of character; the one as something bestowed by God and imputed to man, the other as something inherent in God and spiritually communicated to man.=**Syn. 1.** See *righteous*.

The rotation of the plane of polarization by certain substances showing circular polarization is called *right-handed* when, to an observer looking in the direction in which the ray is moving, the rotation is clockwise—that is, in the same direction as that of the hands of a clock; if in the opposite direction (counter-clockwise), the rotation is called *left-handed*. Similar phonetic changes (*-thm-* > *-tm-* > *-m-* or *-sm-*) appear in the etymology of *arithmetic* (ML. *arismetrica*, OF. *arismetique*, etc.), *abysm* (*abime*), etc. The ML. (and hence the OF.) term was applied especially to accentual verse, as distinguished from quantitative or classical verse, and so came to denote verse with agreement of terminal sound, and in general any poems having this characteristic. About 1550, with the increasing interest in classical models and nomenclature, the E. *rime*, *ryme* came to be spelled, often, *rhime* or *rhyme*, *rithme* or *rythme*, and then *rhithme* or *rhythme*, the latter forms being at length pronounced as if direct derivates of the Latin *rhythmus*, < Gr. *ῥυθμός*. The OF. and other Rom. forms (*rime*, *rima*), when taken into Teut., seem to have been partly confused with a similar native Teut. word, ME. *rime*, AS. *rīm*, OS. **rīm* (in *unrīm*), OHG. *rīm*, number, ON. *rīm*, computation; which word (itself erroneously connected, by some etymologists, with Gr. *ἀριθμός*, number) accordingly disappeared or became merged in the borrowed word. The spelling *rhyme* or *rhime* is erroneous, as *isle*, *feign*, *deign*, *indict*, etc., are erroneous, in that a letter not belonging to the English word has been irregularly inserted in imitation of a remote foreign original.] **1.** Thought expressed in verse; verse; meter; poetry; also, a composition in verse; a poem, especially a short one; a tale in verse.

See *homœoteleuton*, and compare *assonance*.

Rime is the rhythmical repetition of letters. Nations who unite arsis and prose accent need to mark off their verses plainly. They do it by *rime*. Other nations shun *rime*. When the riming letters begin their words, it is called *alliteration*. When the accented vowels and the following letters are alike, it is called *perfect rime*. When only the consonants are alike, it is called *half rime*.

See *male*[1].—**Neither rime nor reason**, neither consistency nor rational meaning; neither sound nor sense; hence, with no mitigating feature or excuse. The phrase occurs under various forms, and especially in plays upon words.

It was a favorite form of verse till the end of the sixteenth century. The following stanza is an example:

And first, within the porch and jaws of hell,
Sat deep Remorse of Conscience, all besprent
With tears; and to herself oft would she tell
Her wretchedness, and, cursing, never stent
To sob and sigh, but ever thus lament
With thoughtful care, as she that, all in vain,
Would wear and waste continually in pain.

In western Europe the disease has prevailed from time to time since the fourth century in extensive epizoötics. From its home on the steppes of eastern Russia and central Asia it has been carried westward by the great migrations and later by the transportation of cattle. The losses in Europe have been enormous. Thus, in 1711–14 1,500,000 beeves are said to have perished, and in 1870–1 30,000 beeves in France alone. The infection (which is probably ultramicroscopic in size [Koch]) may be transmitted directly by sick animals or indirectly by manure, or by persons and animals going from the sick to the well. It may be carried a short distance in the air. Its vitality is retained longest in the moist condition. The disease, after a period of incubation of from three to six days, begins with high temperature, rapid pulse, and cessation of milk-secretion. This latent period is followed by a congestion of all the visible mucous membranes, on which small erosions or ulcers subsequently develop. About 90 per cent. of all attacked die in from four to seven days after the appearance of the disease. If the animal survives, one attack confers a lasting immunity.

A commercial measure of staves, or wood prepared for casks, containing four shocks, or 240 pieces.—**Abdominal ring.** See *abdominal*.—**Annular ring,** in *bot.*, one of the concentric layers of wood produced yearly in exogenous trunks. Such rings result from the more porous structure of the wood formed in spring as compared with the autumn growth, a difference attributed to less and greater tension of the bark at the two seasons. In the exogens of temperate regions, on account of the winter rest, these zones are strongly marked; in those of the tropics they are less obvious, but the same difference of structure exists in them with few if any exceptions, save in cases of individual peculiarity. In temperate climates a double ring is exceptionally produced in one season, owing to a cessation and resumption of growth, caused, for example, by the stripping of the leaves. It is a question whether some, especially tropical, trees do not normally form semiannual rings corresponding to two growing seasons. Somewhat similar rings are formed, several in a season, in such roots as the beet. These have no reference to seasons, but result, according to De Bary, from the successive formation of cambium-zones in the peripheral layer of parenchyma. See *mantle*.—**Tracheal rings,** in *anat.* and *zoöl.*, the rings or hoops of cartilage (sometimes of bone) which are situated in the walls of the windpipe and serve to keep that air-passage permanently distended. Such rings are usually of hyaline cartilage and very elastic, but may ossify more or less completely. They are numerous, closely succeeding one another along the course of the trachea. They are frequently incomplete in a part of their circumference, or otherwise irregular, when, like the corresponding bronchial rings, they are known as *half-rings*. In animals whose necks undergo notable lengthening and shortening in different attitudes of the head, the rings provide for a corresponding extension and contraction of the trachea, as notably in birds, whose tracheal rings are regularly beveled alternately on the right and left sides, so as to slide over one another when the windpipe is contracted in retraction of the neck. (See cut under *tracheal*.) Tracheal rings are normally much alike in most of the length of the windpipe, but commonly undergo special modifications at each end of that tube (see *cricoid, n.*, and cut under *pessulus*); less frequently several rings are enlarged and consolidated in a dilatation called the *tympanum*. The word *river* is not connected with the word *rivulet*.] **1.** A considerable body of water flowing with a perceptible current and bearing more or less waste of the land, in a definite course or channel, usually without cessation during the entire year. Some watercourses, however, are called *rivers*, although their beds may be almost, or entirely, dry during more or less of the year. As water must find its way downward, under the influence of gravity, wherever the opportunity is offered, most rivers reach the ocean, which is the lowest attainable level, either independently or by uniting with some other stream; but this process of joining and becoming merged in another river may be repeated several times before the main stream is finally reached. In interior arid regions, rivers end in lakes or sinks, or wither away on a forward sloping surface. Some such regions are basins inclosed by mountains, as in central Asia; but others are open to the sea, and the rivers end simply from lack of water supply, as in the Argentine Republic. As a general rule, the river which heads farthest from the sea, or which has the longest course, retains its name, while the affluents entering it lose their identity when merged in the larger stream. There are various exceptions to this, one of the most remarkable of which is the Mississippi, which retains that name to its mouth, although the affluent called the Missouri is much longer than the Mississippi and somewhat larger at the junction. The water carried by rivers is rain or melted snow, a part of which runs on the surface to the nearest rivulet while the rain is falling, or immediately after it has fallen, while a larger part consists of that rain-water which, falling upon a permeable material, such as sand, gravel, and open-textured rock, sinks beneath the surface for a certain distance, and then, more or less slowly, according to the permeability of the superficial material, the extent to which it is saturated with water, and the nature and position of the impermeable beds, issues as a spring at a stream-head or in a stream-channel. Were the surface everywhere entirely impermeable, the rainfall would be carried at once to the nearest rivers, and disastrous freshets would be the rule rather than the exception in regions of large rainfall. Many of the largest rivers head in high mountain regions, where the precipitation is chiefly or entirely in the form of snow, which can melt only gradually, so that disastrous floods are thus prevented, while the winter's precipitation in many regions is stored away for summer's use, extensive tracts being thus made available for habitation which otherwise would be deserts. The size of a river depends chiefly on the orographical features and the amount of rainfall of the region through which it flows. Thus, the Amazon is the largest river in the world because the peculiar topography of South America causes the drainage of a vast region (over two million square miles) to converge toward one line, and because the whole course of that river and its branches is through a region of very large rainfall. The Orinoco, although draining an area less than one fifth of that of the Amazon, is navigable for fully 1,000 miles, and is, when full, over three miles wide at 560 miles from its mouth, because it drains a region of extraordinarily large precipitation. The Missouri-Mississippi, on the other hand, although draining an area nearly as large as that of the Amazon, is very much inferior to that river in volume at its mouth, because it flows for a considerable part of its course through a region where the precipitation is very small, while it is not extraordinarily large in any part of the Mississippi basin. The area drained by any river is called its *basin;* but this term is not generally used except with reference to a river of considerable size, and then includes the main river and all its affluents. The edge of a river-basin is the watershed, in the United States frequently called the *divide*, and this may be a mountain-range or an entirely inconspicuous elevation of the surface. Thus, for a part of the distance, the divide between the Mississippi basin and that of the Great Lakes is quite imperceptible topographically. Exceptionally some large rivers (as the Amazon and Orinoco) inosculate with each other. In *phys. geog.* rivers are classified according to their origin as *consequent, subsequent, obsequent, resequent, insequent, antecedent, superposed* (or *inherited*, or *epigenetic*); according to their stage of development as *young, mature, old* (see *valley*), *revived, adjusted, captured, beheaded* (see *divide*), *betrunked*, etc. See these terms.

2. A narrow salt-water lagoon inclosed from the ocean by a sand-reef, as Indian river, behind the reef of Cape Canaveral. It may be navigable or not; the right to use it may be purely public or it may be private property; it may arise from streams, or constitute the outlet of a lake; it may be known by the appellation of *river* or by some other name—these particulars not being material to its legal character as a river. *Bishop.*

★**rivet**1 (riv'et), *n.* [Early mod. E. also *ryvet*, *revet;* < OF. *rivet*, *rivect*, a rivet, also the welt of a shoe, < *river*, clench, rivet, tuck in (bedclothes), F. *river*, clench, rivet; cf. Sc. dial. *riv*, clench (Aberdeen), sew coarsely (Shetland), < Icel. *rifa*, tack together, stitch together (Skeat). Cf. *rivet*1, *v.*] A short metallic malleable pin or bolt passing through a hole and so fastened as to keep pieces of metal (or sometimes other substances) together; especially, a short bolt or pin of wrought-iron, copper, or of any other malleable material, formed with a head and inserted into a hole at the junction of two or more pieces of metal, the point after insertion being hammered broad so as to keep the pieces closely bound together. Large rivets are usually hammered or closed up (riveted) when they are in a heated state, so as to draw the pieces more firmly together by the contraction of the rivet when cool. It is in this manner that boilers, tanks, etc., are made. Small rivets are frequently riveted cold. Instead of being closed by hammering, rivets are now often riveted by means of powerful machinery, which makes better joints than can be made by hand, and executes the work far more quickly. In some kinds of metal-work, as armor, the metal pin is movable in a slot, allowing one of the plates of metal to slide over the other for a certain distance. Compare *Almain-rivet*.

riveting-machine (riv′et-ing-ma-shēn″), *n.* A power-machine for forcing hot rivets into position in metal-work and heading them. Such machines consist essentially of a die and anvil; and in typical forms of the machine the work to be riveted is supported over the anvil, the hot rivet is put in place in the hole, its end resting in a die-socket in the anvil, and the horizontal die advances, squeezes the rivet into place, and shapes both heads at the same time. Riveting-machines are made in a great variety of forms for both light and heavy work. In some forms the anvil and die are both movable and are operated by air, steam, or hydraulic power. Some are portable, and are suspended by chains from a crane, so that the machine can be brought to the work instead of carrying the work to the machine. A recent American machine employs an anvil and a riveting-hammer operated by compressed air and delivering a series of rapid blows instead of a direct pressure, and thus more nearly copies hand-work. Riveting-machines are sometimes called by special names, as the *girder riveter*, *keel riveter*, etc.

Four or five species are recognized by recent authors. *R. lævis*, a native of tropical and subtropical America, has been introduced into Asia and some African islands. It is an erect smooth or hairy herb with shrubby base, 6 or 8 feet high, or in some forms much smaller, producing many two-forked and two-furrowed branches. It bears alternate slender-petioled thin ovate leaves, and slender pendulous racemes of small reddish-white flowers, followed by red pea-like berries. In the West Indies it is called *hoop-withe*. Another species, *R. humilis*, extending into the United States, is known as *blood-berry*, also as *rouge-berry* or *rouge-plant*, from a use made of its fruit before it becomes dry. Both plants, especially the latter, are somewhat cultivated for ornament.

These algæ occur in both running and standing fresh water—occasionally forming a blue-green scum on stagnant pools; and there are a few species in brackish or salt water.

It is more like a warbler than like a thrush, only about 5½ inches long and 9 in extent of wings; the upper parts are olive-green; the forehead, sides of the head, front of the neck, and fore part of the breast are yellowish-red (whence the name *redbreast*). It is an abundant and familiar British bird, widely distributed in other parts of the Palearctic region. The song is rich, mellow, and finely modulated. The nest is placed on the ground, in herbage or moss, generally under a hedge or bush. The eggs are usually five or six in number, pinkish-white freckled with purplish-red. This robin is a common figure in English nursery tales and folk-lore.

A strange world where the *robin* was a little domestic bird that fed at the table, instead of a great fidgety, jerky, whooping thrush. *O. W. Holmes*, Old Vol. of Life, p. 172.

2. The red-breasted or migratory thrush of North America, *Turdus migratorius* or *Merula migratoria*, one of the most abundant and familiar of North American birds: so called from the reddish-brown color of the under parts, which, however, is very different, both in hue and in extent, from that of the European redbreast. This robin is 10 inches long and 16 in extent of wings. The upper parts are slate-color with an olive shade; most of the under parts are chestnut-red; the vent-feathers are white, with dusky markings; the head is black, with white marks about the eyes and white streaks on the throat; and the tail is blackish, usually marked with white at the ends of the outer feathers. The bill is mostly yellow. The robin inhabits the whole of North America; it is migratory, feeds on insects, worms, berries, and other fruits, and breeds at large throughout its range, building a large strong nest of hay and mud on a bough, and laying from four to six uniform greenish-blue eggs, 1¼ inches long by ¾ inch broad. Also, familiarly, *robin-redbreast*.

American Robin (*Merula migratoria*).

3. With a qualifying term, one of numerous warbler-like or thrush-like birds, more or less nearly related to or resembling either of the foregoing: as, the blue-throated *robin*. (See *Cyanecula*, and cut under *bluethroat*.) Some of these terms are book-names, others are casual transfers of the word *robin* by English residents in various parts of the world, especially India and Australia. In the latter region are various flycatchers (*Muscicapidæ*) of the genus *Petrœca* and its subdivisions, some of which are called *robins*, as the scarlet-breasted, *P. multicolor*, peculiar to Norfolk Island. Some of the Asiatic chats of the genus *Pratincola* are known as *Indian robins;* these are related to the British whinchat and stonechat, and do not particularly resemble the true robin of England. Others, recently separated generically under the name *Erythromyias*, inhabit Java, Sumatra, Borneo, and other islands of the same zoögeographical region, and resemble the true robin, as *E. dumetoria* and *E. muelleri*. The red-breasted flycatcher, *Muscicapa* (*Erythrosterna*) *parva*, which ranges from central Europe into India, bears a striking resemblance to the true robin. Among other Indian robins, loosely so called, may be noted one sometimes specified as the *water-robin*. This is a flycatcher, *Xanthopygia fuliginosa*, originally described by Vigors in 1831 as *Phœnicura fuliginosa*, and commonly catalogued as *Ruticilla fuliginosa* (after G. R. Gray); but it does not belong to the same family as the robin, nor to the same genus as the redstart. It inhabits the Himalayan region, and ranges widely in China and India. It has been placed in 5 different genera, two of which, *Rhyacornis* of Blanford and *Nymphæus* of A. O. Hume, were specially framed for its reception.

4. The robin-snipe or red-breasted sandpiper, *Tringa canutus:* a clipped name among gunners. Also *beach-robin*. See *knot*², 1.—5. The sea-robin or red-breasted merganser, *Mergus serrator*. The leaves are unequally pinnate with stipulate leaflets, and are furnished with a pair of bristle-shaped stipules, or of short stout spines in their place. The flowers are white or rose-purple, borne in conspicuous racemes. There are 5 or 6 species, 2 of them little-known Mexican trees, the others native in the southern and central United States. roc[1] (rok), *n.* [Also *rock*, *rok*, *ruc*, *ruck*, *rukh*; = G. *roc* = Sw. *roc*, *rok* = Dan. *rok* = It. *ruch*, *rochi* (Florio), < Ar. Pers. *rukh*, a roc. Cf. *rook*[2].] A fabulous bird of prey of monstrous size, famous in Arabian mythology, and corresponding to the Persian simurg. There is no certain basis of fact upon which the myth of the roc rests. The most colossal birds of which we have any knowledge are the dinornithic moas of New Zealand and the Madagascar æpyornithic elephant-birds. The largest known rapacious bird (the roc figures as a bird of prey) is the *Harpagornis*, which may have been able to kill a moa, though certainly not to fly away with one. The most plausible speculation bases the roc on the *Æpyornis*. See the quotation.

On the 27th of January, 1851, Isidore Geoffroy Saint-Hilaire read before the Parisian Academy of Sciences a paper, in which he described two enormous eggs and part of the metatarsus of a bird which he called *Æpyornis maximus*. . . . This brought again to mind the old story of the famous Venetian traveller, Marco Polo, who located the *ruc* or *roc*, the giant bird of the Arabian tales, upon Madagascar, and related that the great Khan of the Tartars, having heard of the bird, sent messengers to Madagascar, who brought back a feather nine spans long, and two palms in circumference. *Stand. 2. *Eccles.*, a close-fitting vestment of linen or lawn, worn by bishops and some others. It reaches to the knees or lower, and has close sleeves extending to the wrists, or is sleeveless. The rochet is a variety of the alb or surplice, the latter differing from both alb and rochet by the fullness of its sleeves. In the Roman Catholic Church the rochet is worn by bishops and abbots, usually under a manteletta, and, as a choir vestment, by some canons. In the Anglican Church the rochet is worn under the chimere—these vestments constituting the distinctive episcopal habit as ordinarily worn in church and in Parliament and Convocation. The lawn sleeves are now made very full, and attached to the chimere, not to the rochet.

rock[1] (rok), *n.* [< ME. *rocke*, *rokke*, < AS. **rocc* (in *stān-rocc*, 'stone-rock') = OF. *roc*, m. (= It. *rocco*, m.), *roke*, usually assibilated *roche* (> ME. *roche*, E. obs. *roach*[2], q. v.), F. *roche*, f., = Pr. *roca*, *rocha* = Sp. *roca* = Pg. *roca*, *rocha* = It. *rocca*, *roccia*, < ML. *roca*, *rocca*, a rock. The Celtic forms, Ir. Gael. *roc*, Bret. *roch*, are from E. or F. Acc. to Diez, prob. < LL. **rupica*, < L. *rupes*, a rock.] 1. The mass of mineral matter of which the earth, so far as accessible to observation, is made up; a mass, fragment, or piece of that crust, if too large to be designated as a *stone*, and if spoken of in a general way without special designation of its nature. When there is such special designation, the term *stone* is more generally adopted, as in *building-stone*, *paving-stone*, *limestone*, *freestone*; or the special designation of the material itself may be used without qualification, as *granite*, *slate*, *marble*, etc. The unconsolidated stony materials which form a considerable part of the superficial crust, or that which is at or near the surface, such as sand, gravel, and clay, are not commonly designated as *rock* or *rocks*; the geologist, however, includes under the term *rock*, for the purpose of general description, all the consolidated materials forming the crust, as well as the fragmental or detrital beds which have been derived from it. Rocks are ordinarily composed of two or more mineral species, but some rocks are made up almost entirely of one species: thus, granite is essentially an aggregate of quartz, feldspar, and mica, while marble usually consists chiefly of carbonate of lime, and sandstone and quartzite chiefly of quartz. The number of varieties of rock, according to the classification and description of lithologists, is very great. The number of names popularly in use for rocks is small: *granite*, *porphyry*, *lava*, *sandstone* or *freestone*, *limestone*, *marble*, and *slate* are terms under one or the other of which by far the largest part of the rocks are commonly classed. (See these words.) More than 600 distinct species of minerals have been described, but a very small number of them occur as essential constituents of rocks: of these, quartz, the feldspars, the micas, the minerals of the augite and hornblende group, talc, chlorite, olivin, and carbonate of lime, with which often more or less of carbonate of magnesia is associated, form the great bulk of the rocks. But there are several other minerals which are quite commonly found as accessory constituents, and sometimes in masses large enough to be worthy of the designation of *rock*: such are garnet, epidote, various oxids of iron, pyrites, apatite, andalusite, leucite, tourmalin, and a few others. Some mineral substances occur in masses of great extent and thickness, but do not play the part of rock-forming minerals: such are salt, gypsum, and the varieties of coal. Rocks are variously classed by geologists. The most general subdivision of them is into *igneous* and *aqueous*: the former are divided into *plutonic* and *volcanic*, according as they have been formed under conditions of depth and pressure, like granite, or have been poured out upon the surface in the manner of lava. The aqueous rocks are also designated as *sedimentary*, *fossiliferous*, or *stratified*. The sedimentary rocks in general are believed to be made up of material resulting from the decay and abrasion of igneous masses, since almost all geologists admit that the crust of the earth has cooled from a state of fusion. Part of the stratified deposits, however,

have been formed through the agency of life, as in the case of the limestones, most of which have been secreted from an aqueous solution by various organisms, and of coal, which is the result of a peculiar kind of decay of vegetable matter. Some rocks have been formed by the simple evaporation of a solution: for instance, rock-salt. The sedimentary rocks are classified for lithological description according to the nature and texture of the materials of which they are made up: they are arranged in the chronological order of their deposition according to the nature of the fossils which they contain. Sedimentary rocks have frequently been greatly changed in character by metamorphosis, by which they have been rendered crystalline, and sometimes made so closely to resemble igneous rocks that their true character can only with the greatest difficulty be made out.

Tennyson, In Memoriam, Conclusion.

Rocking bob. Same as *balance-bob.*—**Rocking stone,** a large block of stone poised so nicely upon its point that a moderate force applied to it causes it to rock or oscillate. Such stones are most common in regions of granite, and especially where it has a marked cuboidal jointing. The quadrangular masses resulting from the weathering of this granite assume spherical forms, since the edges and angles waste away more rapidly than the sides, and a rocking stone is not infrequently the result. There are several rocking stones in the granite region of Devonshire and Cornwall, where they are known as *loggans*, *loggan-stones*, or *loggan-rocks*. The best-known of these is near Castle Treryn, St. Levan; it is about 17 feet long, and weighs about sixty-five tons. The term is also applied to balanced boulders which have been left by the melting of glacial ice.

The same cause affects granitic cliffs, rounding the surfaces formed by the "joints," and often leaving detached blocks on the brow of the cliff; and they also give rise to the *Rocking Stones* common in granite districts.
Prestwich, Geol., I. 56.

=**Syn. 1** and **2.** *Rock*, *Shake*, *Swing*, *Roll*. *Shake* expresses a quicker, more sudden, and less uniform motion than the others: as, to *shake* a tree or a carpet; his knees *shook*. *Rock* expresses the slow and regular motion to and fro of a body supported below—as a cradle upon *rockers*, or a *rocking* stone—or at the sides. *Swing* expresses the regular and generally slow motion to and fro, or around and around, of a body supported or held at one end, generally above: as, the *swinging* of a pendulum, a censer, a sword. *Roll* is sometimes used of an irregular motion to and fro, suggesting the *rolling* over of a round log: as, a *rolling* walk; the *rolling* of a ship in the trough of the sea. The figurative uses of these words are akin to their literal meanings: a ship *rocks* when the wind is steady on the aft quarter; it *swings* about its anchor with the change of the tide; it *shakes* with each blow from a heavy wave.

Small rock-basins are common on the exposed surface of the rocks in various countries, and they are most frequently met with in granitic regions, especially in Cornwall and Devonshire, where they have been worn out by atmospheric erosion, assisted by the tendency to a concentric structure which granite frequently exhibits. These rock-basins have been, and still are by some, ascribed to the Druids. A cylindrical tube of pasteboard or metal filled with a mixture of niter, sulphur, charcoal, etc., which, on being ignited at the base, propels the tube forward by the impact of the liberated gases against the atmosphere. Rockets are used for various purposes. (*a*) In war, when the apparatus generally consists of a sheet-iron case filled with a composition such as is described above, and a head which may be solid, or hollow and filled with a bursting-charge. (*b*) Life-rockets, used for carrying a line over a wreck, and thus establishing communication between the ship and the shore. The Russian rocket has a short stick attached to the base and armed with a hook which slides in a groove on the under side of the rocket-stand and engages the ring of the chain attached to the line as the rocket leaves the stand. The German system comprises five-centimeter and eight-centimeter rockets and eight-centimeter anchor-rockets, all of which have long chains attached to the rocket-stick at one end and to the line at the other. The English system consists of double Boxer rockets placed end to end in a single metallic case, having a stick fastened to one side of the case. The Hooper rocket is a modification of the Hale war-rocket, and was very unsatisfactory in its results. All these rockets have metallic cases, and are fired by means of fuses. The uncertainty of their flight and their liability to deterioration by transportation and storage have prevented their adoption for life-saving purposes in the United States. the same composition, but with a conical head containing stars of various ingredients and colors, and a quantity of powder which, when the rocket has attained its greatest height, bursts the cylinder, when the ignited stars spread through the air and cast a brilliant or colored light producing a beautiful effect. These rockets are used in signaling or for mere pyrotechnic display. Rockets are kept point foremost in their flight by means of a stick projecting behind, which acts in the same way as the shaft of an arrow.

To the head of such *rockets* may be placed petards, balls of fire, granadoes, etc., and so may be applied to warlike affairs. *Mathematical Recreations* (1674).

2. The lever by which a forge-bellows is inflated.—**Congreve rocket**, a large rocket having a shell of sheet-iron and carrying charges of canister-shot, bullets, and other missiles Sir William Congreve, who first introduced this weapon into warfare, and from whom its name is derived, caused sizes to be constructed ranging from 12 to 32 pounds, with sticks for the larger sizes 20 feet in length. The first notable use of Congreve rockets was at Copenhagen in 1807, and among the then-existing means of attack it proved a very formidable weapon. The composition used in these rockets is saltpeter, sulphur, and charcoal; and they sometimes have a metal head loaded with a bursting-charge very destructive in a fortress or town. Modern improvements in ordnance have supplied more efficient means of attack, and rockets are now used in warfare chiefly as a means for signaling.

rococo (rō-kō′kō), *n.* [< F. *rococo*, appar. a made word, based perhaps, as usually explained, on *rocaille*, rockwork (on account of the rockwork which figures in the style), < *roche* (ML. *roca*), a rock: see *rock*[1].] A variety of ornament originating in the Louis-Quatorze style and continuing with constantly increasing inorganic exaggeration and extravagance throughout the artistic degeneracy of the Louis-Quinze. It is generally a meaningless, though often a very rich, assemblage of fantastic scrolls and crimped conventional shell-work, wrought into irregular and indescribable forms, without individuality and without expression apart from its usually costly material and surroundings. The style has a certain interest from its use in a great number of sumptuous European residences, and from its intimate association with a social life of great outward refinement and splendor. Much of the painting, engraving, porcelain-work, etc., of the time has, too, a real decorative charm, though not of a very high order in art. Hence *rococo* is used attributively in contempt to note anything feebly pretentious and tasteless in art or literature. Compare *baroque*.

Rococo.—An interior in Schloss Bruchsal, Baden, Germany. (From "L'Art pour Tous.")

The jumble called *rococo* is, in general, detestable. A parrot seems to have invented the word; and the thing is worthy of his tawdriness and his incoherence.

(*e*) A long, light, tapering, elastic pole used in angling, to which the line is attached, now usually made in adjustable sections or joints, and fitted with guides and a reel. There are eight woods commonly used for rods, of which four are solid (greenheart, hickory, ash, and willow) and four are hollow (East Indian bamboo, Carolina and West Indian cane, white cane, and jungle-cane). Rods have also been made of hard rubber and of steel. Jointed rods are made in three or four pieces, of which the largest and heaviest is the butt, and the slenderest is the tip. The joints are fitted with metal rings or ferrules, and with small rings called *guides* to receive the line. The reel is stepped into the butt, near its end, or otherwise suitably attached, as by a reel-plate. The special makes of rods are very numerous, and their names almost equally so. Besides being named and classed according to the material of which they are composed, as *bamboo rod*, etc., they are commonly identified with the name of the fish for which they are specially designed: as, *salmon-rod, trout-rod, bass-rod*, etc. All rods are, however, divisible into three classes, according to their make and purpose. These are (1) the *fly-rod*, which is long, slender, tapering, tough, and highly elastic; (2) the *trolling-rod*, which is comparatively short, stout, and stiff; and (3) the *bait-rod*, which is a mean between the other two. Fly-rods are most used, with artificial flies. Split-bamboo rods are now manufactured for all kinds of angling. See *fly-rod*, and cut under *reel*. (*f*) An instrument for measuring.

2. In *mech.*, any bar slender in proportion to its length, particularly such a bar used as a brace or a tie between parts for connecting them, or for strengthening a connection between them. The term is used in a very indefinite manner, depending entirely upon individual judgment or caprice. What some would call a rod would by others be called a bar.

See cut under *palatoquadrate*. Also called *Meckel's cartilage*.—**Napier's rods** (or **bones**), a contrivance, described by John Napier (1550–1617) in his Rabdologia (1617), for facilitating large calculations in multiplication or division for those who do not perfectly know the multiplication table. It consists of a number of rods made of bone, ivory, horn, wood, pasteboard, or other convenient material, the face of each of which is divided into nine equal parts in the form of little squares, and each part, with the exception of the top compartment, subdivided by a dexter diagonal line into two triangles. These nine little squares contain the successive multiples of the number in the first, the figures in the tens' place being separated by the diagonal line from that in the units' place. A sufficient number of rods must be provided for each of the headings 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, so that by placing the proper rods side by side any number may be seen at the top, while the several multiples occupy, in order, the eight lower compartments; when the multiple consists of two figures these are placed one on each side of the diagonal line. There is also a rod called the *index-rod*, the squares on which are not subdivided into triangles. To multiply, for example, the number 6789 by 56: Place four of the rods together, so that the top numbers form the multiplicand; then look on the index-rod for 6, the first number of the multiplier, and on the corresponding compartments of the four rods the following disposition of figures will be found ranged in the two lines formed by the triangles of each square.....

Division is performed in an analogous manner. Napier's rods are still made, though they are of little use.—**Parallel rod**, in locomotives having more than one pair

Also called *coupling-rod*.—**Pedal rod.** See *pedal*.—**Perforating rods of Sharpey.** Same as *Sharpey's fibers* (which see, under *fiber*).—**Rod-and-cone layer of the retina.** See *retina*.—**Rod license.** See *license*.—**Rods of Corti,** the pillars of the arches of the organ of Corti. The external rods which form the outer pillars are shorter and less numerous than the inner rods. They consist of a cylindrical striated body with an expanded base; the upper extremity is curved, and has somewhat the shape of the head of a bird; the back part fits into a cavity between the heads of two or more inner rods; while the bill-like process projects toward the reticular membrane. The inner rods have a striated body and an expanded base; the heads have a concavity which receives the outer rods, and a process entering into the composition of the membrana reticularis. The arches thus formed support the outer and inner hair-cells. Also called *pillars of Corti*.—**Setting-out rod,** a guide or gage used in making window-frames, doors, etc.—**Split rod.** (*a*) One of the rods into which plates of wrought-iron are cut by means of slitting rollers, to be afterward made into nails. Rodentia (rō-den′shi-ạ), *n. pl.* [NL., < L. *rodentia* (sc. *animalia*), neut. pl. of *roden(t-)s*, ppr. of *rodere*, gnaw: see *rodent*.] An order of ineducabilian placental diphyodont *Mammalia*; the gnawers. The brain has a relatively small cerebrum, leaving much of the cerebellum and olfactory lobes exposed, and the corpus callosum has no well-defined rostrum in front. The placentation is discoidal-deciduate. The limbs are ambulatorial, variously modified for running, leaping, climbing, or swimming. The condyle of the lower jaw has its long axis longitudinal, and is not confined in a special socket, but glides back and forth, so that the lower jaw can be put forward and backward as well as moved up and down. The molar teeth are typically ridged on their crowns in various patterns; they are nearly always 3 in number above and below on each side. The premolars are small or few, often none. There are no canines. The incisors are large, strong, heavily enameled on their front surface, scalpriform or beveled to a sharp edge, and grow continually from persistently open pulps; their roots traverse much or nearly all of the bones of either jaw, in the arc of a circle. The typical number of incisors is 2 above and below, or one pair of upper and under front teeth; exceptionally, as in the rabbit tribe, there are small supplementary upper incisors, crowded together and concealed behind the functional pair. In some groups, as *Arvicolinæ*, the molar teeth are perennial, like the incisors. There being no canines, and the premolars being few and small, if any, there is a great gap between the front and the back teeth. The typical number of teeth is 16, which obtains with few exceptions throughout the murine series of rodents; in one genus there are only 12. In the hystricine series there are normally 20 teeth, in one genus 16. In the sciurine series the teeth are always either 20 or 22; in the leporine series there are 26 or 28. This order is by far the largest one among mammals, and of world-wide distribution; its numerous members are adapted to every kind of life. They are mostly of small size, a rabbit being far above the average; the beaver, porcupine, or coypou is a very large rodent, and the capibara is a giant. The order is divisible into 3 suborders: (1) *Hebetidentata*, enormal or blunt-toothed rodents, exceptional in having 4 lower incisors, and extinct; (2) *Duplicidentata*, subnormal or double-toothed rodents, with 4 upper incisors: these are the hares, rabbits, and pikas; and (3) *Simplicidentata*, normal or simple-toothed rodents, with only 2 incisors above and below. The last fall in 3 series: (1) *Hystricomorpha*, the hystricine series, including the porcupines and very numerous related forms, chiefly South American, as the capibara, coypou, cavies, viscachas, chinchillas, octodonts, etc. (see cuts under *capibara*, *coypou*, *rabbit-squirrel*, *porcupine*, and *Plagiodon*); (2) *Myomorpha*, the murine series, including rats and mice of all kinds (see cuts under *mouse*, *Muridæ*, and *rice-field*); and (3) *Sciuromorpha*, the sciurine series, or the squirrels, spermophiles, marmots, beaver, etc. (see cuts under *Arctomys*, *beaver*, and *prairie-dog*). In addition, the duplicident rodents are (4) *Lagomorpha*, the leporine series, the same as the suborder *Duplicidentata*. (See cut under *Lagomys*.) Many fossils of all these groups are known. There are 20 or 21 families of living rodents, and 174 genera. The order corresponds to the Linnean *Glires*, and is still often called by that name. Also called *Rosores*. See cuts under *castor*, *Leporidæ*, and *scalpriform*.

Such rolling-mills sometimes bear special names, as a rail-mill, wire-rolling mill, etc. The essential feature of a rolling-mill is a set or train of steel rollers placed either in pairs one over the other, as in a two-high train, or in a group of three, as in a three-high train. The heated metal direct from the furnaces is presented to these rollers and is drawn through between the trains. It is at once caught on the other side and repassed between the rollers, each passage between them being called a *pass*. In a two-high train the rollers are stopped and reversed at each pass. In a three-high train the rollers turn constantly in one direction, the return pass being between a different pair of rollers from the pair first passed through, the middle roller, however, always being one of either pair. The distance between the rollers is regulated by screws at the ends. The section given to the metal in passing through the rollers is determined by the shape of the rollers, whether flat or grooved, it being possible to produce in this way bars having a great variety of sections, adapted for independent or structural uses. The rolling-mill serves also to some extent to clear the metal passed through it from impurities. Small rolling-mills with tapering rollers are used to roll short flat metal bars into rings, the passage between the rollers expanding the outside more than the inside edge, and thus causing the strip to assume a curved form. See cut under *roll*, 2 (*a*).
